## **1. Schematic diagram of experimental set**

**Fig. S1**

## **2. Wave length of the UV lamp**

**Fig. S2**

## **3. TEM images of $\text{Fe}_3\text{O}_4@\text{SiO}_2@\text{TiO}_2$ with different ammonia content**

**Fig. S3**

## **4. TEM images of pea-like $\text{Fe}_3\text{O}_4@\text{SiO}_2@\text{TiO}_2$ with different diameter of mixing paddle**

**Fig.S4**

## **5. Formation mechanism of pea-like $\text{Fe}_3\text{O}_4@\text{SiO}_2@ \text{TiO}_2$**

The formation of a polymerized  $\text{TiO}_2$  via sol-gel process including hydrolysis and condensation process of TIPO is mainly controlled by the concentration of ammonia while maintaining other parameters [1,2]. As shown is **Fig.S5**, there are four models

observed for nucleation and growth of  $\text{TiO}_2$  on the surface of  $\text{Fe}_3\text{O}_4@\text{SiO}_2$  spheres under different ammonia concentration.

In the **Model 1**, due to the concentration of ammonia is very low, the hydrolysis and condensation rate of TIPO is so slow that the heterogeneous nucleation is difficult to proceed. Therefore, there is no  $\text{TiO}_2$  nanoparticles on the surface of  $\text{Fe}_3\text{O}_4@\text{SiO}_2$  spheres [3]. Increasing the concentration of ammonia slightly, which can promote the hydrolysis and condensation of TIPO, thus the concentration of titanium oligomers increases. When the concentration of titanium oligomers is more than the critical concentration of heterogeneous nucleation, the heterogeneous nucleation of  $\text{TiO}_2$  shell produces on the  $\text{Fe}_3\text{O}_4@\text{SiO}_2$  spheres surface (**Model 2**). With the increase of concentration of titanium oligomers which is higher than the supersaturated concentration, the small  $\text{TiO}_2$  nuclei can be formed both on the surface of  $\text{TiO}_2$  shell and the solution system (**Model 3**). Furthermore, when the initial contents of ammonia are too high, a continual cascading of  $\text{TiO}_2$  nuclei in addition to growth occurs *via* diffusion and polymerization of titanium oligomers to the  $\text{TiO}_2$  nuclei. Meanwhile, under the mechanical force-driven [4], the pea-like structured  $\text{Fe}_3\text{O}_4@\text{SiO}_2@\text{TiO}_2$  particles are formed (**Model 4**).

**Fig.S5**

**6. TEM images of PLYS-Fe<sub>3</sub>O<sub>4</sub>@TiO<sub>2</sub> spheres with different concentration of NaOH**

**Fig.S6**

**7. TEM and SEM images of PLYS-Fe<sub>3</sub>O<sub>4</sub>@TiO<sub>2</sub>**

**Fig.S7**

**8. EDS of PLYS-Fe<sub>3</sub>O<sub>4</sub>@TiO<sub>2</sub>**

The integrated energy dispersive X-ray spectroscopy (EDS) shows that the content of Ti, Fe, O is 34.35%, 13.17% and 40.61%, respectively.

**Fig. S8**

**9. Iron leaching test**

The iron leaching from the PLYS-Fe<sub>3</sub>O<sub>4</sub>@TiO<sub>2</sub> into the solution were measured using an inductively coupled plasma atomic emission spectrometer (ICP-AES; Perkin Elmer 5300DV).

**Fig.S9**

## 10. TOC removal efficiency calculation

The removal percentage of TOC was calculated by using Eq. S1

$$\text{TOC removal} = \left(1 - \frac{\text{TOC}_t}{\text{TOC}_0}\right) \times 100\% \quad (1)$$

where  $\text{TOC}_0$  and  $\text{TOC}_t$  are the TOC values at initial and time of the photocatalytic photo-Fenton process, respectively. As shown in **Fig.S10**, 65.2 % TOC was removed at pH 7 in 2h.

**Fig.S10**

**Table S1**
