We fabricated the sample (recorded as sample-1) prepared in a similar way of Ni-Fe-P-350 electrode in the absence of metal sources in hydrothermal reaction. After the same annealing process with the existence of NaH_2PO_2, the XRD test of this sample (recorded as sample-1) was performed (Fig. S11a). The weak diffraction peaks could be ascribed to the Ni_2P (PDF 03-0953) except the peaks of Ni foam (PDF 04-0850), indicating that the Ni foam is partially phosphatized. Then we tested the electrochemical performance of this sample, as shown in Fig. S11b-d. The specific areal capacities of sample-1 are 0.4 to 0.14 C cm^{-2} at current densities of 5 to 50 mA cm^{-2}. The electrochemical properties of the Ni foam after phosphorization are increased than before. Although the Ni-Fe-P-350 nanosheets grow uniformly on the substrate, the open space of the porous network can still store the electrolyte and permeate the surface of

phosphatized Ni foam in the actual electrochemical reactions. So this phosphatized Ni foam could make some positive contributions to the specific capacity of Ni-Fe-P-350 electrode in the electrochemical tests.

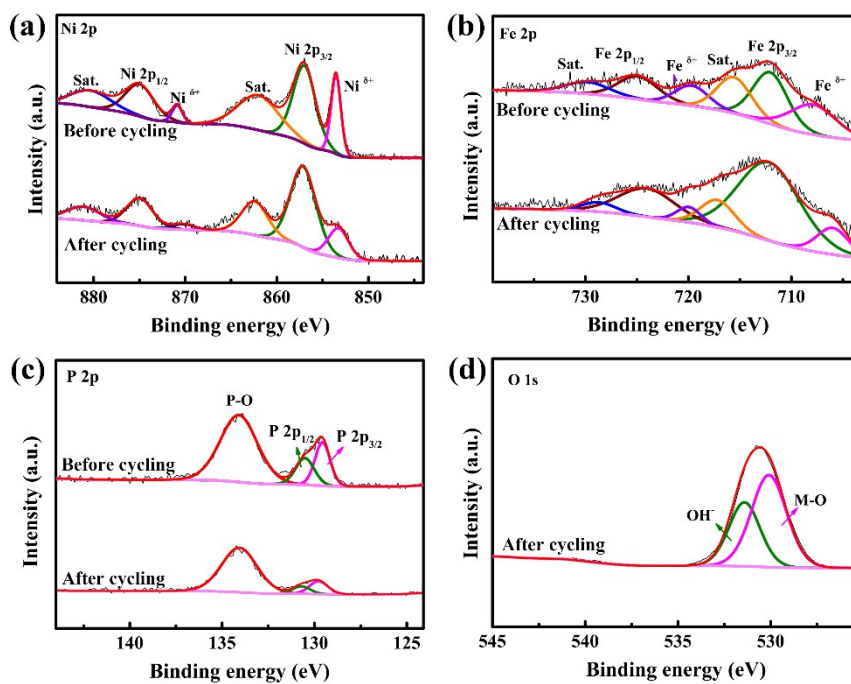

Fig. S15 XPS spectra of (a) Ni 2p, (b) Fe 2p and (c) P 2p of the Ni-Fe-P-350 sample before and after cycling test. (d) XPS spectrum of O 1s of the Ni-Fe-P-350 sample after cycling test.
Fig. 16 TEM investigations of the Ni-Fe-P-350 sample after cycling test. (a and b) TEM images (the inset of b shows the SAED pattern of the metal phosphide). (c) HRTEM image. (d) SAED pattern of the generated metal oxo/hydroxyl species.

Fig. S15 shows the XPS spectra of the Ni-Fe-P-350 sample before and after cycling test. As shown in Fig. S15a, the decreased peaks of $Ni^{\delta+}$ at 853.6 and 870.6 eV can be observed after the cycling test compared with the peaks before cycling, indicating that the surface of the phosphide have been oxidized.[1] The $Fe^{\delta+}$ peaks after cycling test shown in Fig. S15b are aslo decreased and the peaks at 712.3 and 724.5 eV increase obviously, which also suggest the oxidation of the surface. The peaks of P $2p_{3/2}$ and P $2p_{1/2}$ (Fig. S15c) which represent the metal-P bonding also exhibit the declined trend. Furthermore, the O 1s spectrum (Fig. S15d) presents two peaks at 530.1 and 531.4 eV which can be ascribed to the oxygen and hydroxyls of the metal oxides/hydroxides generated on the surface after the cycling test.[2] The XPS analyses suggest that the surface oxidation occurred and the metal oxides/hydroxides generated after cycling test. While the metal phosphide still exist in this electrode. These results are similar with the previous report.[3]

Fig. S16 shows the TEM investigations of the Ni-Fe-P-350 sample after cycling test.

The nanosheet of the sample still maintains the porous structure (Fig. S16a and b), which is in good agreement with the SEM results (please see Fig. S13a and b in the Supporting Information). The inset of Fig. S16b displays the SAED pattern and serial annulus express planes of (111), (300), (211), (310) and (311) of the still remaining metal phosphides, indicating the polycrystal structure. The lattice fringe in HRTEM image (Fig. S16c) shows a distance of 0.21 nm which represents the specific facet of metal oxides/hydroxides, suggesting that the oxides/hydroxides have been formed on the surface of the sample.[1, 2, 4] The SAED pattern shown in Fig. S16d illustrates the poor crystallinity and the low content of the metal oxo/hydroxyl species on the surface. The TEM results also verify the surface oxidation and the metal phosphide core still exist, which accord well with the XPS analysis. And the XRD pattern (please see Fig. S14b in the Supporting Information) of the Ni-Fe-P-350 sample after cycling test shows no diffraction peaks of metal oxides/hydroxides. We infer that this is because of the poor crystallization behavior and lower content of metal oxides/hydroxides in comparison with the phosphides, so XRD test cannot detect them. This phenomenon was also reported in another previous article.[5]

The XPS and TEM analyses prove the surface oxidation of the metal phosphide electrode after the cycling test. And the contents of the formed metal oxides/hydroxides are very small. The metal phosphides exist widely as core and host materials beneath the oxidation layer. So the metal phosphides are the main electroactive materials for the contribution of capacitance. In addition, there probably has generated a new metal-P/oxides/hydroxides (M-P/O/OH) heterojunction on the surface of the still existing metal phosphide core, which likely improves the electrochemical activity of the electrode.[4, 5] The electrochemical performance of the Ni-Fe-O and Ni-Fe LDH electrodes (please see Fig. 5 in the manuscript) could attest this point. Without the metal phosphides as the core and host materials, the Ni-Fe-O and Ni-Fe LDH electrodes with poor conductivity exhibit the not satisfactory performance. The metal phosphides may be the ideal and conductive core to accelerate the electron transfer in the electrochemical reactions.[6, 7] In short, the underlying metal phosphides have an important role in the enhancement of the electrochemical behavior for supercapacitors

and make a major contribution for the excellent capacitance.

Table. S1 The Ni-Fe based phosphides with different Fe contents and the corresponding labels.

Fe/Ni molar ratios (%)	12%	20%	33%	39%	47%
The labels of samples	NFP-1	NFP-2	NFP-3	NFP-4	NFP-5

Table S2. Electrochemical performance of the Ni-Fe-P electrode compared with the similar reported materials.

Electrode materials	Specific capacity	Stability (Cycles)	Ref.
Ni-Fe-P	1358 C g^{-1}/ 3018 F g^{-1} (5 mA cm^{-2})	94.7% (10000 cycles)	This work
NiCoP/NiCo-OH	1100 F g^{-1} (1 A g^{-1})	88% (1000 cycles)	[8]
Ni$_x$P$_y$	2544 F g^{-1} (2 A g^{-1})	90.9% (5000 cycles)	[9]
CuCoP	1946 F g^{-1} (5 mA cm^{-2})	92.7% (6000 cycles)	[10]
Cu$_3$P	300.9 F g^{-1} (2.5 mA cm^{-2})	/	[11]
NiCoOP@C	2638 F g^{-1} (1 A g^{-1})	84% (3000 cycles)	[12]
NiCoP	1427.5 F g^{-1} (1 A g^{-1})	71.8% (3000 cycles)	[13]
Ni-P	1597.5 F g^{-1} (0.5 A g^{-1})	71.4% (1000 cycles)	[14]
Ni-P@NiCo$_2$O$_4$	1240 F g^{-1} (1 A g^{-1})	/	[15]
NiCoP	1153 F g^{-1} (1 A g^{-1})	97% (7000 cycles)	[16]
Ni$_{12}$P$_5$	949 F g^{-1} (1 A g^{-1})	81% (2000 cycles)	[17]
Co$_2$P	416 F g^{-1} (1 A g^{-1})	/	[18]
CoP	447.5 F g^{-1} (1 A g^{-1})	84.3% (5000 cycles)	[19]

Table S3. Electrochemical performance of the Ni-Fe-P//RGO HSC device compared with the similar reports.

HSC device	Maximum energy density	Maximum power density	Stability (Cycles)	Ref.
Ni-Fe-P//RGO	65.1 Wh kg^{-1}	19.7 kW kg^{-1}	91.5% (10000 cycles)	This work
NiCoP/NiCo-OH //porous carbon	34 Wh kg^{-1}	11.6 kW kg^{-1}	92% (1000 cycles)	[8]
Cu$_3$P //CNT	44.6 Wh kg^{-1}	17 kW kg^{-1}	81.9% (5000 cycles)	[11]
NiCoOP@C //AC	39.4 Wh kg^{-1}	7.5 kW kg^{-1}	70.6% (7000 cycles)	[12]
NiCoP //AC	32 Wh kg^{-1}	5.6 kW kg^{-1}	91.8% (3000 cycles)	[13]
Ni-P //AC	29.2 Wh kg^{-1}	8 kW kg^{-1}	84.5% (1000 cycles)	[14]
Ni-P@NiCo$_2$O$_4$//AC	13.3 Wh kg^{-1}	5.7 kW kg^{-1}	78.3% (10000 cycles)	[15]
NiP@CoAl-LDH //AC	37.18 Wh kg^{-1}	4.68 kW kg^{-1}	95.5% (4000 cycles)	[20]
NiCoP //AC	32.9 Wh kg^{-1}	8.5 kW kg^{-1}	83% (5000 cycles)	[21]
Co$_2$P//graphene	24 Wh kg^{-1}	6 kW kg^{-1}	97% (6000 cycles)	[18]
Ni$_8$-Co$_1$-P//AC	22.8 Wh kg^{-1}	4.32 kW kg^{-1}	100% (5000 cycles)	[22]
Ni$_3$P$_2$O$_8$//Fe$_3$P$_2$O$_8$·8H$_2$O	32.6 Wh kg^{-1}	3.35 kW kg^{-1}	81% (10000 cycles)	[23]
CoP//AC	19 Wh kg^{-1}	8.5 kW kg^{-1}	96.7% (5000 cycles)	[19]
