1. Search Criteria and Data Retrieval

All reported unique TM-carbonyl bonds from crystal structures with R-factors <7.5% were catalogued according to metal and the TM-C and C≡O bond-lengths placed in arrays using CSD software.¹ Where sufficient data existed, subsets with different coordination numbers, oxidation states, and *trans*-ligands were analysed.

To identify the trends, data sets were divided into subsets with different TM-C bond lengths using increments of ~0.01 Å. For each of these increments the C≡O bond lengths were averaged and the confidence interval (CI) on the mean calculated using the formula $CI = \alpha\sigma N^{-1/2}$, for a 95% confidence interval $\alpha = 1.96$, σ represents the standard deviation, and N is the number of observations.^{2,3} As a dataset gets larger you are more certain of its mean, as the standard deviation or dataset variation is larger you are less certain of the mean. This formula represents this quantitatively with respect to the assumption of a normal distribution and is detailed in many statistical text-books.^{3,4}

a. Separation of Oxidation States

Oxidation states were separated manually on the basis of authors reports.

b. Separation of *trans*-ligands

Figure S.1. Search criteria used to identify *trans*-ligands.

All observations containing a carbonyl group and the *trans*-ligand of interest were recorded, as was the angle between the two groups. The structures were designated “*trans*” or “*cis*” when this angle was 150-180° or 90-100° respectively those structures with angles in the range 100-150° were excluded, due to the ambiguity of the classification.

2. Scatter plots for Osmium

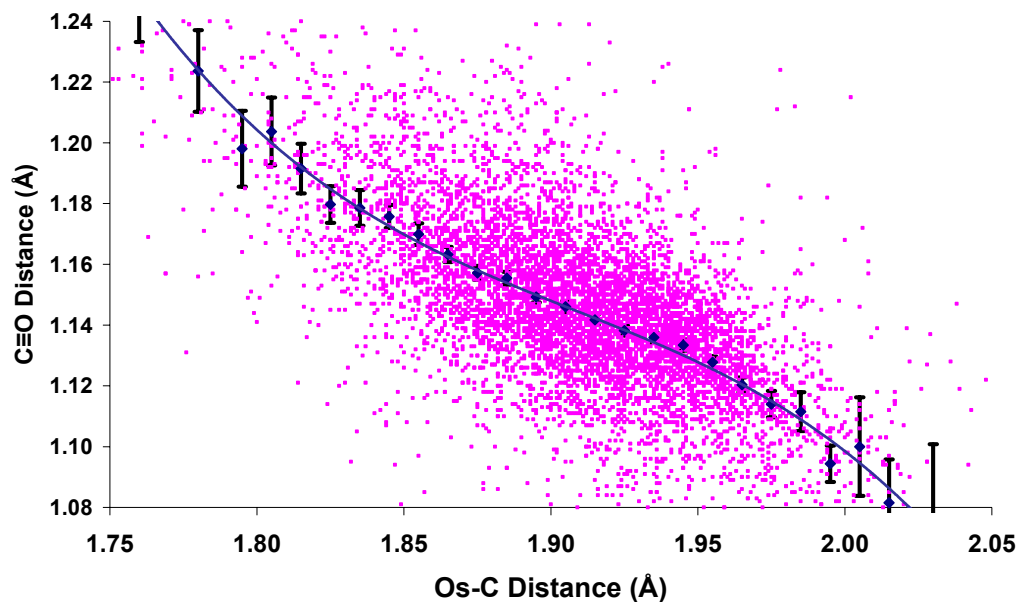

Figure S.2. Plot of C≡O bond-length vs. Os-C bond-length (Å). Error bars represent 95% confidence interval on the mean over the range the data-point is given for.

Figure S.3. Plot of C≡O bond-length vs. Os-C bond-length (Å), error bars represent 1 standard deviation.

3. Plot of M-C Distance vs C≡O Distance not included in paper and colour figures.

Figure S.4. Plot of C≡O bond-length vs. M-C bond-length (Å), for the sets of 6-coordinate first row transition-metal carbonyl complexes. Error bars represent the 95% confidence intervals on the mean, over the range the point is given for. Data sets are based on the following numbers of 6-coordinate TM-carbonyl interactions Ni(175), Co(3,329), Fe(9,231) Mn(3,426), Cr(2,798), V(60), and Ti(5).

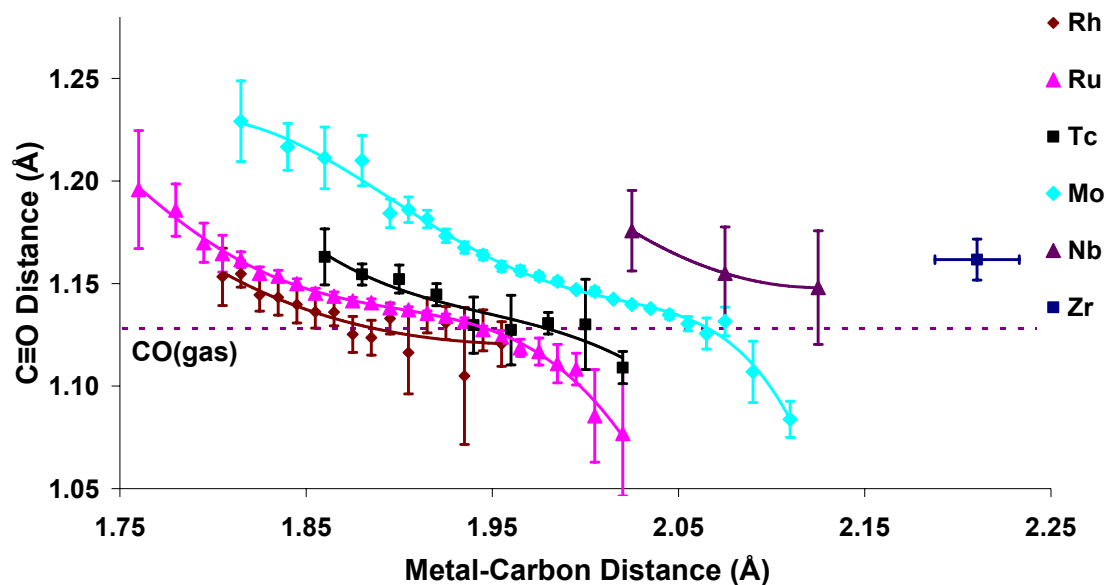

Figure S.5. Plot of C≡O bond-length vs. M-C bond-length (Å), for the sets of 6-coordinate second row transition-metal carbonyl complexes. Error bars represent the 95% confidence intervals on the mean, over the range the point is given for. Data sets are based on the following numbers of 6-coordinate TM-carbonyl interactions Zr(3), Nb(9), Mo(3,240), Tc(118), Ru(6196) and Rh(244)

Figure S.6. Plot of C≡O bond-length vs. Metal-Carbon bond-length (Å), for the sets of 6-coordinate third row transition-metal carbonyl complexes. Error bars represent the 95% confidence intervals on the mean, over the range the point is given for. Data sets are based on the following numbers of 6-coordinate TM-carbonyl interactions Hf(3), Ta(13), W(6,202), Re(4,838), Os(6,552), Ir(857) and Pt(73).

Nb	7	9	0(0.0%)	(-1) 1
Ta	12	13	0(0.0%)	(-1) 2
Cr	848	2,798	93(10.9%)	Mostly 0 and 1
Mo	755	3,240	29(3.8%)	Mostly 0 and 1
W	1206	6,206	75(6.2%)	Mostly 0 and 1
Mn	723	3,426	185(25.5%)	Mostly 0 and 1
Tc	31	118	1(3.2%)	Mostly 0 and 1
Re	993	4,838	164(16.5%)	Mostly 0 and 1
Fe	1956	9,231	1566(80.0%)	[+2/+3] 189 (2.0%) Mostly 0 and 1
Ru	1643	6,196	1112(67.7%)	[+2/+3] 358 (5.8%) Mostly 0 and 1
Os	1412	6,552	1223(86.6%)	[+2/+3] 118(1.8 %) Mostly 0 and 1
Co	1011	3,329	979 (96.8%)	Mostly 0 and 1
Rh	145	244	116 (80.0%)	Mostly 0 and 1
Ir	373	857	196 (52.5%)	Mostly 0 and 1
Ni	23	175	21 (91.3%)	0
Pd	2	Not derived	2(100%)	0
Pt	60	73	60 (100%)	0

Figure S.15. The Structure ACREOS10, the carbonyl bond lengths are numbered {M-L/C≡O}⁵. This structure is very typical of all the members of the datasets and illustrates the variation observed in M-C bond-lengths in a single complex,

5. The Effect of Oxidation State of the Metal on Trends

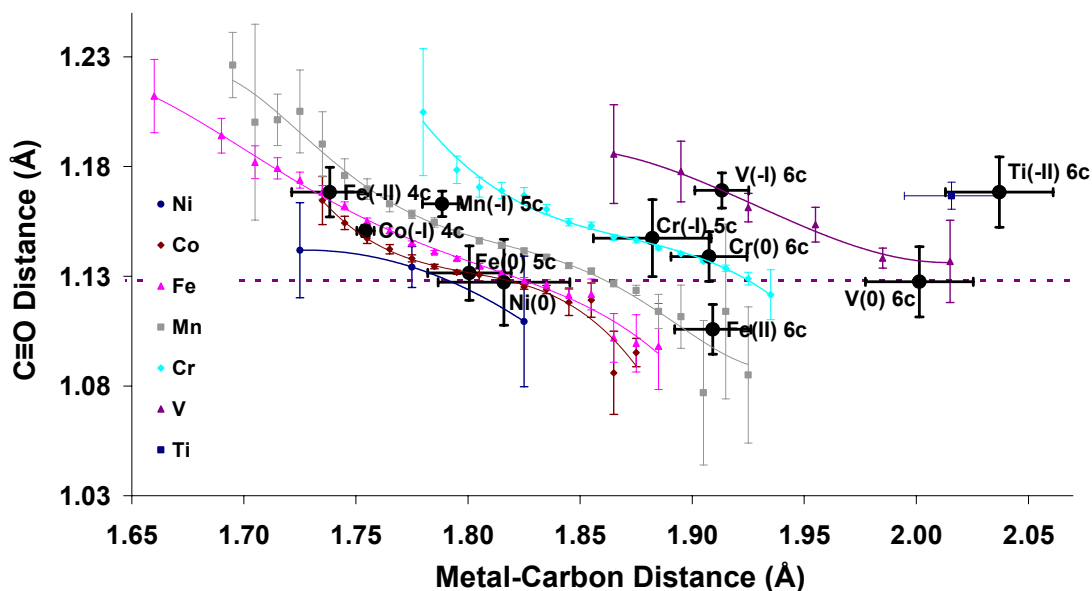

Figure S.16. Homoleptic Metal-Carbonyl Complexes superposed on the first row transition metals. Large ranges in oxidation states are observed, due to the propensity of the complexes to be 18 electron species

6. Homoleptic Metal-Carbonyl Species

To understand mutual ligand effects, it is advantageous/preferable to first examine coordination spheres that are not effected by them. The best way to do this is through the small subset of compounds containing only carbonyl ligands. This small subset of the larger datasets comprising <0.4% of the data is important for two reasons: Firstly, in a homoleptic species there can on average be no net polarization of d-orbitals toward or away from other ligands. Secondly, the oxidation state of the metal is more obvious than in mixed ligand systems which may involve multiple metal-metal bonds. It is also important to consider this

in terms of the proportions of the dataset, which ligand systems dominate and in which regions, homoleptic systems give as a definite point in this scheme of things.

Figure S.17. The Structural Data reported thus far for all Homoleptic Metal-Carbonyl Species. Figure 8.14 illustrates the experimental relationship between C≡O bond-length and the C≡O stretching frequencies, as well as the relationship between oxidation state and vibrational frequencies in homoleptic metal-carbonyl complexes.

7. The Effect of Other Ligands in the Coordination Sphere

a. *trans*-ligands

Figure S.18. Effect of *trans*-donors in Group 8 metals Fe, Ru and Os.

Figure S.18 represents the “average” effect of *trans* donors across the Os data-sets. From this data set the series $\text{NC} < \text{Os} < \text{PR}_3 < \text{CR}_3 < \text{H} < \text{CO}$ is derived and it represents the average response of the *trans* donor. It does not necessarily mean these donors only exhibit bonding in the observed regions, rather that there is a propensity to observe more of these compounds in certain regions of the curves.

b. Other Ligands in the Coordination Sphere

i. Effect of Coordination Number

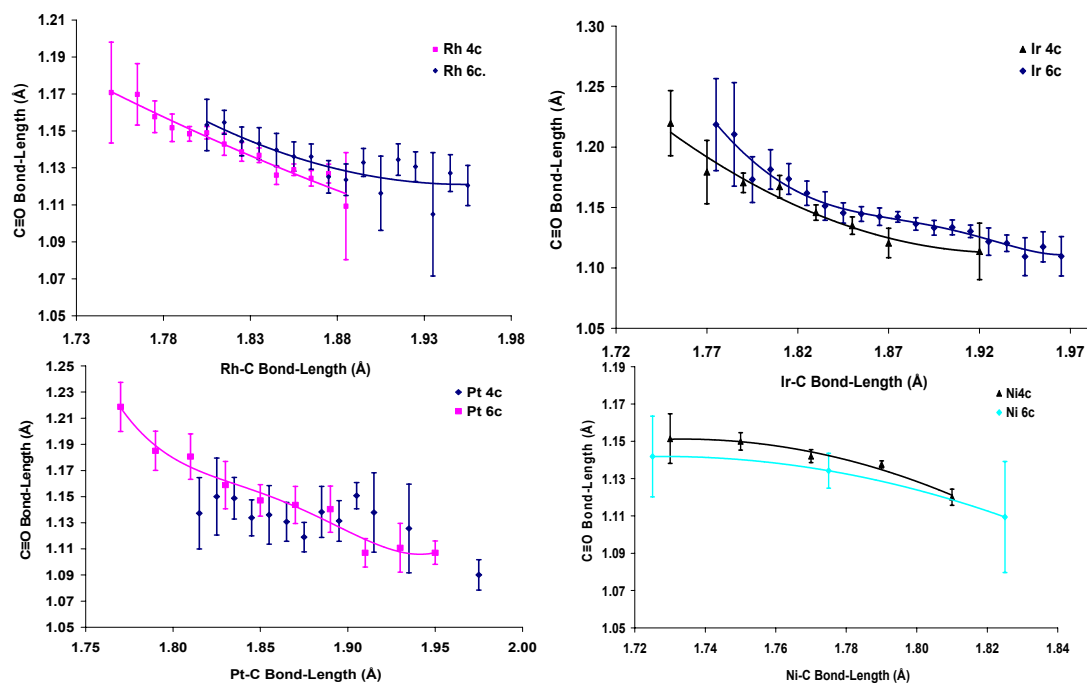

Figure S.19. Comparison of Different Coordination Numbers

Figure S.20. Comparison of Different Subsets of the Fe-Data Set. With there relative numbers of structures. *Many numbers of different coordination, the datasets used are currently the same size due to array limitations in our programs.

It is clear from Figure S.6 that whilst the trends are not completely independent of coordination number they are too a good approximation. In all cases we observe 4c. species to have shorter M-C bond lengths than 6c. species, this is probably a steric effect across the series. The difference between 4c and 6c is in each case less than the difference between the elemental centres.

8. The Exclusion of Metal-Metal Bonds

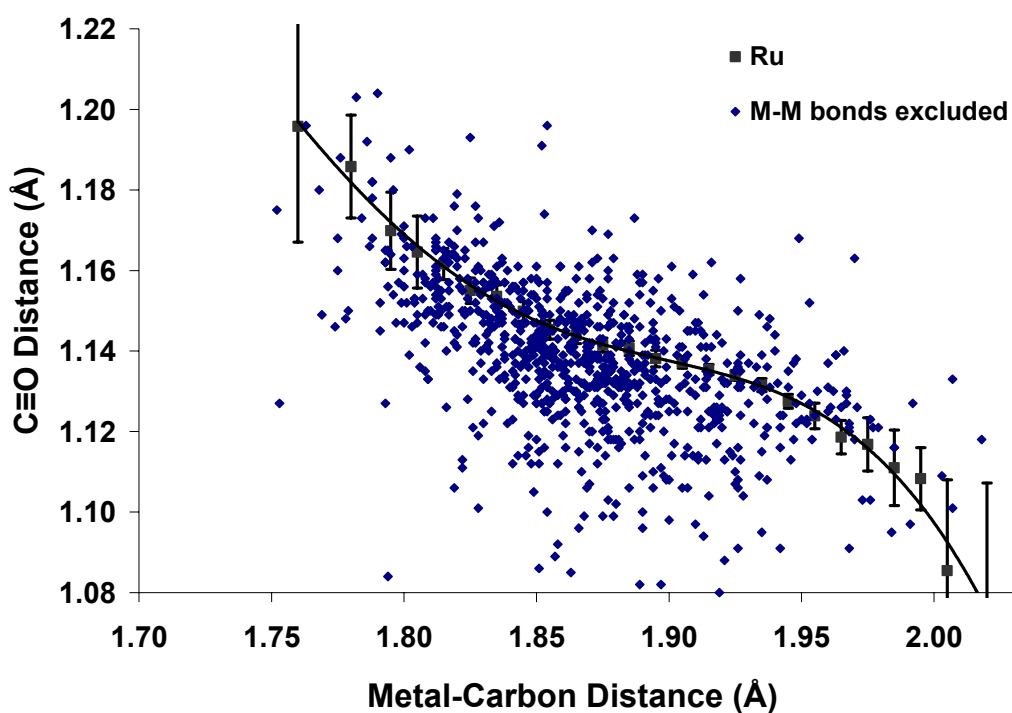

Figure S21. Ruthenium Trend plotted with a scatter plot representing the exclusion of all Metal-Metal bonds.

9. Tables of Data

Table 3. Data for Homoleptic Metal-Carbonyl Species
