Gas sensors properties experiments:

For the fabrication of gas sensors, the In₂O₃ powders were mixed and ground with adhesive in an agate mortar to form paste. The paste uniformly coated an alumna tube on which a pair of Au electrodes was previously printed, and dried at 100 °C for 2 h in air, and then sintered at 600 °C for 1 h in air. At last, a Ni-Cr heating wire was inserted. The gas sensors were aged at 300 °C for 240 h in air in order to improve their stability. A stationary state gas distribution was used for the test of gas sensing properties. The chamber was firstly purged by air until a steady baseline of the sensor resistance was reached. Then the test vapor ethanol was injected using a syringe. The gas sensitivity of the sensor in this paper is defined as $S = R_a/R_g$; R_a , resistance in air, R_g , resistance in test gas. The response time is expected as the time required for sample variation

conductance to reach 90% of the equilibrium value following an injection of the test gas, and the recovery time is the time necessary for the sample to return to 10% above original conductance in air after releasing the test gas.

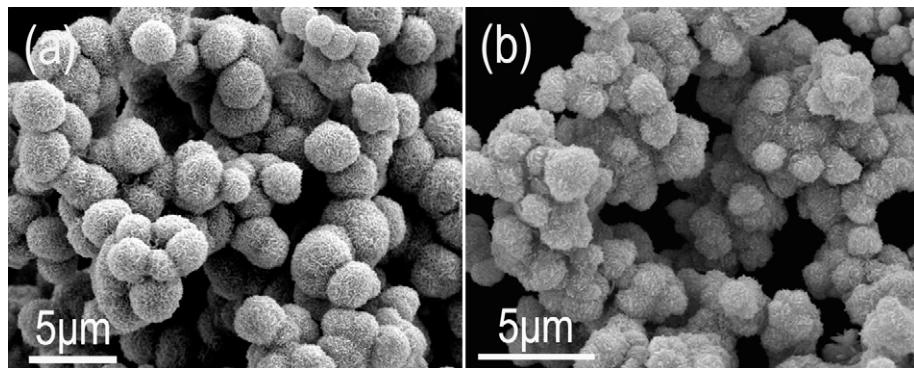

Fig. S1 SEM images of In₂O₃ products prepared at different DMF concentrations at 180 °C for 24 h, (c) DMF = 1.5 ml and (d) DMF = 3.0 ml.
