A. TS12 : $\text{ONF}_3 \leftrightarrow \text{FONF}_2$ isomerisation

A key isomerisation on the $[\text{ONF}_3]$ potential energy surface (PES) is the 1,2-F-migration, connecting the ONF_3 and FONF_2 isomers. It was proposed by Antoniotti and Grandinetti (2002) as the source of the OF radicals observed earlier by Sorokin (1998). However, as discussed in the main paper, the transition state they proposed was characterized by us as the umbrella inversion of the nitrogen centre in FONF_2 , and hence does not connect to the ONF_3 global energetic minimum. Despite numerous attempts at finding the true isomerisation transition state, however, we were likewise unable to locate a saddle point corresponding to the 1,2-F-shift.

To elucidate the matter, we characterized the relevant section of the PES, i.e. the migration pathways of a F atom between the nitrogen and oxygen centre. To this end, we performed a large set of constrained geometry optimizations, fixing the position of the F atom relative to the O–N atom bond, but leaving all other degrees of freedom unconstrained. The resulting two-dimensional section of the PES yields the minimum-energy PES for F-migration between the ONF_3 and FONF_2 energetic minima. The constrained coordinates are the perpendicular distance of the F atom from the N–O bond axis, $y = D(\text{NO--F})$, and the position of the F-atom along that axis, $x = D(\text{N--F})$, where we set N equal to position 0.0, and O along the positive side of the axis.

In this coordinate system, the F_3NO minimum is located approximately at $x = -0.6 \text{ \AA}$, $y = 1.1 \text{ \AA}$; while *trans*- F_2NOF is located at $x = 1.7 \text{ \AA}$, $y = 1.4 \text{ \AA}$. At small y values, i.e. with small $D(\text{NO--F})$, the F-atom is forced into the electron cloud along the N–O bond, causing high

potential energy values. At large separation, i.e. at large negative or positive x-values and/or at large y values, the geometries essentially correspond to the $F_2NO + F$ dissociation limit. We found that the energetically most favourable F-migration always involved a symmetric position of the two non-migrating F-atoms on the N-atom, one on each side of the N–O–F plane, such that an F-migration would preserve the plane of symmetry. Figure SI-1 shows the resulting potential energy surface cross-section (without ZPE-corrections), with energies in kcal mol^{-1} relative to the F_3NO energetic minimum.

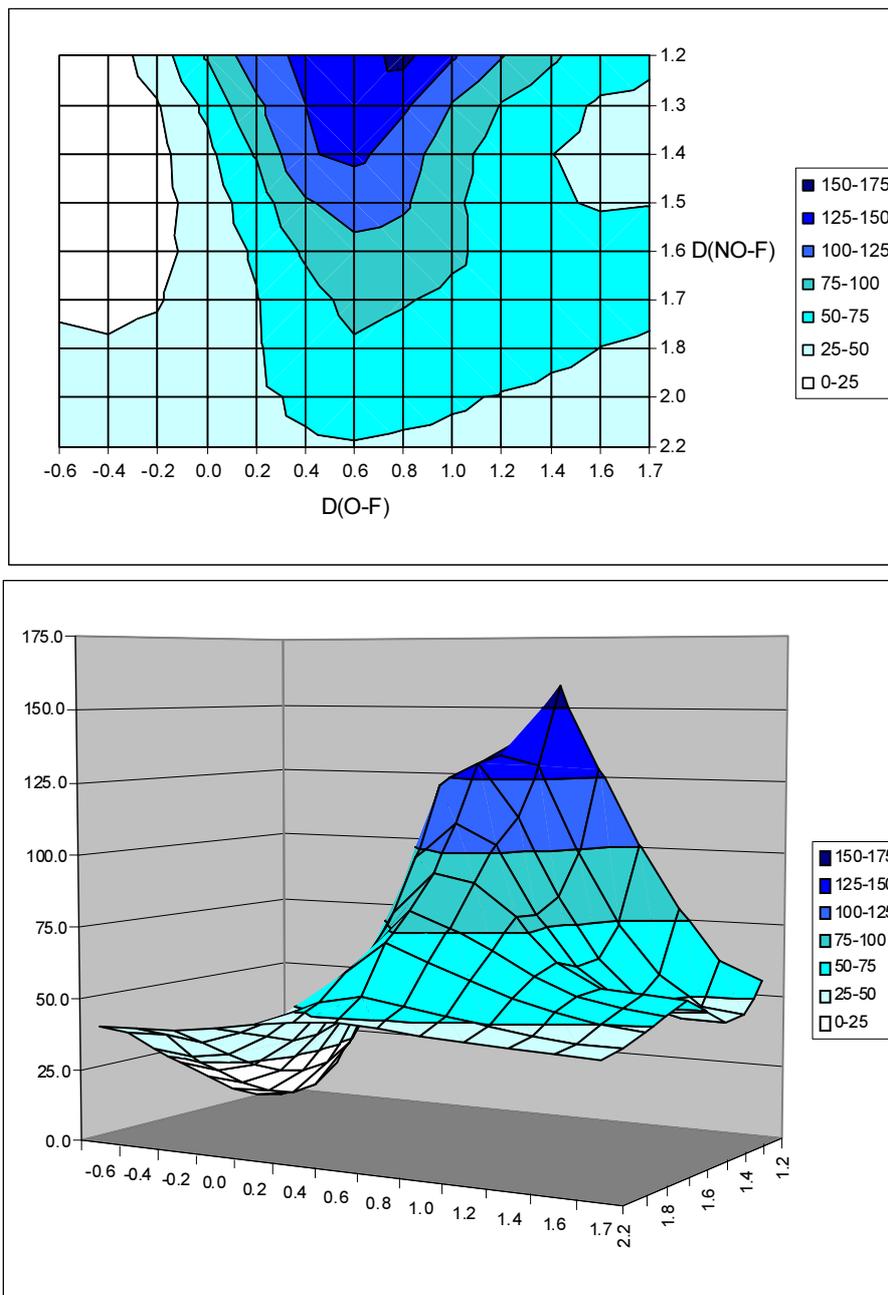

Fig. SI-1: Potential energy surface for the migration of an F-atom (kcal/mol)

This potential energy surface differs strongly from the shape one expects to see for a regular isomerisation (an example of which is shown in Fig SI-2 for a 1,2-H-migration) At the position where one would expect to see a saddle point, roughly at $D(\text{NO-F}) \sim 1.6 \text{ \AA}$ and $D(\text{O-F}) \sim 0.6 \text{ \AA}$, the very low dissociation energy to $\text{F}_2\text{NO} + \text{F}$ lowers the energy at larger F-separation, to the point that the PES shows two convex energy cross-sections: one along the traditional reaction coordinate for F-migration, and another dissociative energy profile perpendicular to it. Hence, no traditional saddle point exists. F-atoms migrating between the N and O centres, then, are energetically and entropically guided towards dissociation. While this does not strictly preclude isomerisation, such a 1-2-F-shift would require a dynamical trajectory that does not follow the lowest-energy path, and hence has a negligible probability compared to the much more favourable dissociation. From this, we conclude that the $\text{ONF}_3 \leftrightarrow \text{FONF}_2$ isomerisation can not carry a significant reaction flux.

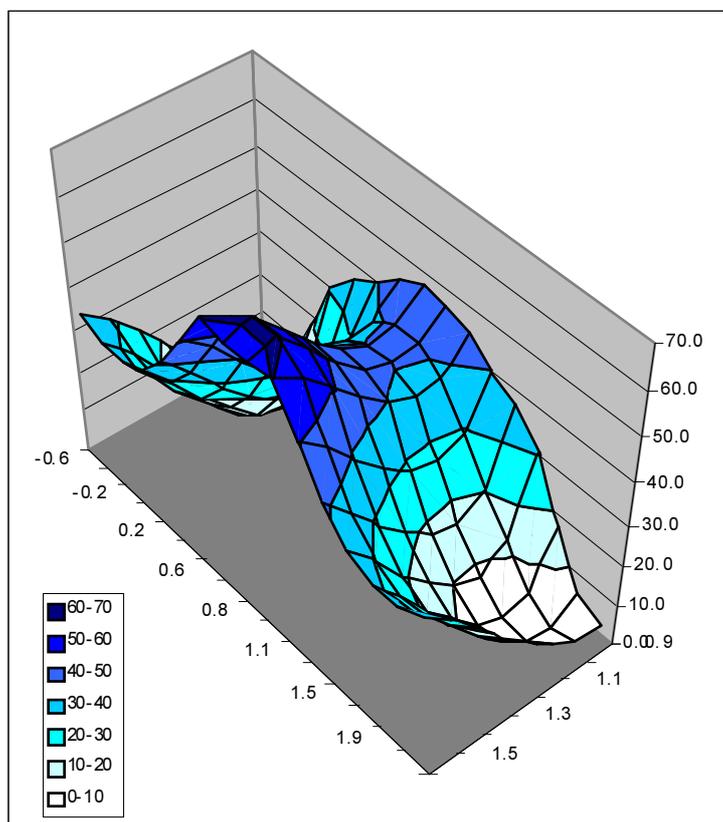

Fig. SI-2: Traditional 1,2-migration showing a saddle point on the PES.

Removal of the potent greenhouse gas NF_3 by reactions with the atmospheric oxidants $\text{O}(^1\text{D})$, OH and O_3 .

Supplemental info. #2 – correlation of $\text{O}(^1\text{D})$ rate constants with ionisation energy.

Terry J. Dillon^{*}, Luc Vereecken, Abraham Horowitz, Victor Khamaganov, John N. Crowley and Jos Lelieveld

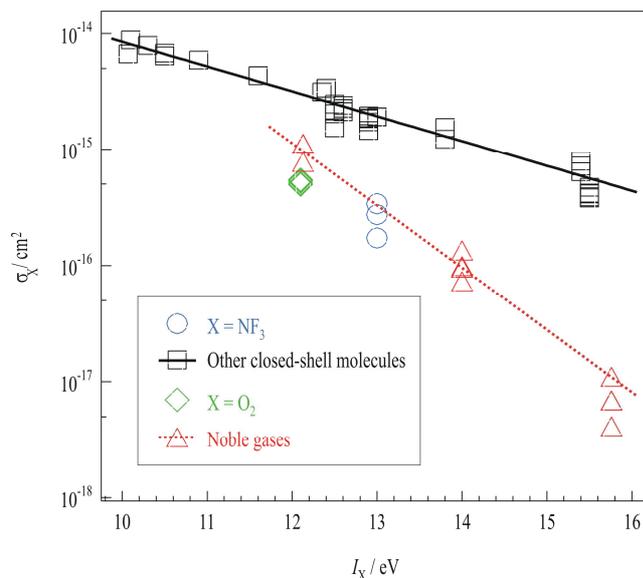

Figure 1 supplemental.

Displays plots of per-collision rate constants against ionisation potential I_X of collider X for reactions of the type $\text{O}(^1\text{D}) + \text{X} \rightarrow (\text{products})$. To compare the $\text{O}(^1\text{D})$ destruction efficiency of various collision partners, thermally averaged reaction cross-sections, σ_X , were calculated using expression (S1)

$$\sigma_X = k_X(298 \text{ K}) / \langle c \rangle \quad (\text{S1})$$

where $\langle c \rangle$ is the mean velocity of the $\text{O}(^1\text{D}) - \text{X}$ collision (from collision theory). The black squares depict literature data for closed-shell molecules (not atoms), with the values already used in ¹⁻² augmented by subsequently published rate coefficient data for $\text{X} = \text{CH}_4$;³ N_2O ;^{4,5} N_2 from this work and ⁵; H_2O and H_2 ;⁶ SO_2F_2 ;^{5,7} and CS_2 and SO_2 .⁷ The solid black line describes an unweighted fit to yield $\sigma_X = 1.20 \times 10^{-12} \exp\{-0.50 I_X\} \text{ cm}^2$. This empirical relationship may be used in conjunction with a literature value for $I_{\text{NF}_3} = 13.0 \text{ eV}$ ⁸ to calculate a predicted $k_2 \approx 1.3 \times 10^{-10} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$, a factor of 5 or so larger than the measurements from ⁷ and in this work. Experimentally derived data for NF_3 (the blue circles) however lies on the correlation line derived from $\text{O}(^1\text{D}) + \text{noble gas}$ data (red triangles, *nb.* $\text{X} = \text{Ne}$ off-scale at $I = 21.56 \text{ eV}$, $\sigma = 5.97 \times 10^{-20} \text{ cm}^2$). An unweighted fit yields $\sigma_X = 3.05 \times 10^{-9} \exp\{-1.23 I_X\} \text{ cm}^2$ (the red dotted line). Note this relationship may be skewed by experimentally derived rate coefficients that were essentially upper-limit values, for this reason no $\text{X} = \text{He}$ data was used.
