Materials and Physical Measurements

All the reagents and $\text{Ln}(\text{NO}_3)_3 \cdot 6\text{H}_2\text{O}$ used were purchased from Aladdin Reagent (Shanghai) Co., Ltd. without further purification.

The relevant data of the elemental analysis described in this article was obtained through the Thermo Flash 2000 elemental analyzer. The infrared spectrum were measured on a Thermo Mattson FTIR spectrometer, and the wavenumber range was $4000\sim 400\text{ cm}^{-1}$. The powder X-ray diffraction (PXRD) patterns were determined on an X-ray diffractometer (Rigaku D/Max 2200PC) in the 2θ range of $5^\circ\sim 50^\circ$. The thermal analysis is performed from 30°C to 800°C at a heating rate of $10^\circ\text{C min}^{-1}$ under N_2 atmosphere on a TGA/NETZSCH STA449C instrument. Nitrogen (N_2) gas sorption measurement was performed on a ASAP2020M&TriStar 3020 surface area analyzer (Micromeritics Instruments Corp., U.S.) at 195 K. The X-ray photoelectron spectroscopy (XPS) measurements were performed on Kratos AXIS Ultra DLD spectrometer. Mercury program version 3.10 were used to simulate the PXRD mode of rare earth complexes. F-7000 fluorescence spectrophotometer was used to obtain the luminescence of the solid powder and the suspension, and the wavelength range was $200\sim 800\text{ nm}$. The luminescence lifetime and quantum yield were recorded on the FLS920 luminescence spectrometer in Edinburgh instrument. The decay curves were fitted by a mono-exponential function: $I = I_0 + A\exp(-t/\tau)$, where I and I_0 are the luminescent intensities at time $t = t$ and $t = 0$, respectively, and τ is defined as the luminescent lifetime. The luminescence quantum yields of the solid samples were determined by the absolute method using the integrating sphere on FLS920 (diameter 150 mm, BaSO_4 coating) of Edinburgh Instrument.

Crystallographic Data Collection and Refinement.

Single crystals of **LZG-Eu** and **LZG-Tb** with approximate dimensions of $0.18 \times 0.12 \times 0.10\text{ mm}^3$ and $0.20 \times 0.16 \times 0.14\text{ mm}^3$ which were suitable for X-ray diffraction were obtained in moderate yield by solvothermal method. Crystal data of **LZG-Eu** was collected on a Bruker APEX-II CCD diffractometer ($\text{MoK}\alpha$ radiation, $\lambda = 0.71073\text{ \AA}$) at 100 K and that for **LZG-Tb** was collected on a Bruker SuperNova diffractometer ($\text{CuK}\alpha$ radiation, $\lambda = 1.54184\text{ \AA}$) at 293 K. Structures were solved by direct methods and refined by a full matrix least-squares technique based on F^2 using the SHELXL 2014 program.¹ All of the non-hydrogen atoms were refined anisotropically. The organic hydrogen atoms were generated geometrically. Disordered phenylic H and uncoordinated carboxyl H for **LZG-Eu** and uncoordinated carboxyl H for **LZG-Tb** were

not located but are included in their formulas. In addition, the disordered crystalline water and DMF molecules in **LZG-Eu** and **LZG-Tb** are difficult to identify, correspondingly, solvate molecules were accounted for by using the program PLATON/SQUEEZE (Spek, 2009) in order to remove the contributions of disordered solvent.² For details about the squeezed material, see cif data in Supporting Information. Therefore, free water and DMF molecules which were determined on the basis of TGA and elemental microanalysis, and the data treated with the SQUEEZE routine within PLATON were added to the molecular formula of **LZG-Eu** and **LZG-Tb** respectively. Drawings of the molecules were performed with the program Diamond.³ Crystallographic data as well as details of data collection and refinement for these complexes are summarized in Table S1, important bond lengths are listed in Table S3. CCDC 2034442 and 2034444 contain the supplementary crystallographic data of **LZG-Eu** and **LZG-Tb**, which can be obtained from the authors or the Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.
