## Investigation of experimental conditions in $\mathbf{G C} \times \mathbf{G C}$

$\mathrm{GC} \times \mathrm{GC}$ employed long ${ }^{1} \mathrm{D}$ column ( 30 m ) and short ${ }^{2} \mathrm{D}$ column $(5 \mathrm{~m})$ enabling fast ${ }^{2} \mathrm{D}$ separation of technical glycol precursor sample (with compounds elution time mostly distributing within a window of 6 s ). As a result, comprehensive analysis was performed within a single run (a single injection). Flow modulator was applied in this approach which requires high ${ }^{2} \mathrm{D}$ flow for effective modulation process $[15,16]$. The outlet flow was thus split to decrease flow to MS by using DS as a splitter [17] as shown in Fig. 1A. The flow was further reduced by use of a longer restrictor with the same I.D. to MS.

## Effects of injection time and ${ }^{2}$ D column flow

With a constant ${ }^{1} \mathrm{D}$ flow of $0.8 \mathrm{~mL} / \mathrm{min}$, different injection times and ${ }^{2} \mathrm{D}$ column flows were investigated in this study. The corresponding $\mathrm{GC} \times \mathrm{GC}$ results were evaluated according to $n_{\mathrm{c}}$ (related to average peak width), total peak area (indicating greater peak focusing effect during the modulation) and the number of identified compounds as shown in Fig. S1. Change of modulator injection time and ${ }^{2} \mathrm{D}$ flow in $\mathrm{GC} \times \mathrm{GC}$ significantly affected ${ }^{2} w_{\mathrm{b}, \text { ave }}$ and total intensity (see ${ }^{2} \mathrm{D}$ width at blob base and total volume data in Fig. S1A and S1B); whilst, ${ }^{1} w_{b, \text { ave }}$ slightly varied as shown by similar ${ }^{1} \mathrm{D}$ width at blob base values plotted in Fig. S1C.

Fig
. S1. Effects of modulator injection time on separation performance using different ${ }^{2} \mathrm{D}$ column flows: 21, 14 and $7 \mathrm{~mL} \min ^{-1}(\star, \Delta$ and $\square$, respectively $)$.

With a constant ${ }^{2} \mathrm{D}$ flow of $21 \mathrm{~mL} \mathrm{~min}{ }^{-1}$, different modulator injection time was applied with the results shown in Fig. S2. Injection time is a period in which a pulse from the end of ${ }^{1} \mathrm{D}$ column is filled into the channel inside the modulator prior to injection onto ${ }^{2} \mathrm{D}$ column. This is a critical parameter in $\mathrm{GC} \times \mathrm{GC}$ which could cause peak dispersion or breakthrough during the modulation process. With the studied conditions, too short injection time ( 0.15 s ) could cause peak fronting as shown by the downward plateau of the peaks located between 20-30 $\min ^{1} t_{\mathrm{R}}$ in Fig. S2; whilst, too long injection time ( 2.40 s ) led to peak tailing (e.g. see the upward plateau of the peaks located between 20-30 $\min { }^{1} t_{\mathrm{R}}$ in Fig. S2). An effective injection time was selected to be 0.60 s reducing effects of peak broadening as shown by the minimum ${ }^{2} \mathrm{D}$ width at blob base $\left({ }^{2} w_{\mathrm{b}, \text { ave }}\right)$ with the 2 D flows of 21 and $14 \mathrm{~mL} \mathrm{~min}^{-1}$ in Fig. S1A

Fig. S2. GC $\times$ GC results obtained by using different injection time ( $0.15-2.40 \mathrm{~s}$ ) using a constant ${ }^{1} \mathrm{D}$ and ${ }^{2} \mathrm{D}$ column flows of 0.8 and $21 \mathrm{~mL} \mathrm{~min}^{-1}$, respectively.

It should be noted that a suitable condition cannot be only that resulting in the best performance, e.g. with the highest $n_{\mathrm{c}}$ at $21 \mathrm{~mL} \mathrm{~min}{ }^{-1}$ of ${ }^{2} \mathrm{D}$ flow and 0.60 s injection time (Fig. S1D) or highest total volume (total intensity) at $7 \mathrm{~mL} \mathrm{~min}^{-1}$ of ${ }^{2} \mathrm{D}$ flow and 0.60 s injection time (Fig. S1D). Other factors need to be taken into account. Use of high pressure at the modulator is required for effective modulation process (e.g. well focused peaks or prevention of leakage), which resulted in high ${ }^{2} \mathrm{D}$ flow. However, low flow is required to preserve lifetime of MS vacuum pump and improved sensitivity, as well as providing effective flow of $20-40 \mathrm{~cm} \mathrm{~s}^{-1}$ with He as carrier gas. The ${ }^{2} \mathrm{D}$ flow
should thus be decreased. However, too low ${ }^{2} \mathrm{D}$ flow also causes ineffective modulation process, e.g. further resulting in weak focussing effect or peak splitting, and peak broadening. With a constant injection time of 0.6 s , different ${ }^{2} \mathrm{D}$ flow was applied with the results shown in Fig. S3.

Fig. S3. $\mathrm{GC} \times \mathrm{GC}$ results obtained by using different ${ }^{2} \mathrm{D}$ column flow ( 21,14 and $7 \mathrm{~mL} \mathrm{~min}{ }^{-1}$ ) using a constant ${ }^{1} \mathrm{D}$ column flow and injection time of $0.8 \mathrm{~mL} \mathrm{~min}^{-1}$ and 0.60 s , respectively.

The result showed improved separation (also with broader peaks) at lower flow due to the increasing void time. However, modulation performance decreased at the lower ${ }^{2} \mathrm{D}$ column flow as can be seen with the significantly broader peak width in ${ }^{2} \mathrm{D}$ separation, see the larger ${ }^{2} \mathrm{D}$ width at blob base ( ${ }^{2} w_{\mathrm{b}, \text { ave }}$ ) by using ${ }^{2} \mathrm{D}$ flow of $7 \mathrm{~mL} \mathrm{~min}^{-1}$ in $\mathbf{F i g} . \mathbf{S 1 A}$, as well as the split peaks (e.g. that after 40 min ) by this flow in Fig. S1. Based on the improved separation performance with significantly high intensity and low ${ }^{2} \mathrm{D}$ flow, $14 \mathrm{~mL} \mathrm{~min}^{-1}$ of ${ }^{2} \mathrm{D}$ flow and 0.60 s of injection time were selected for further analysis with compound identification.

Fig. S4. Venn diagram showing the number of identified compounds in Table 1 using $\mathrm{GC} \times \mathrm{GC}$ and the comprehensive $\mathrm{H} / \mathrm{C}$ MDGC techniques.
