2. Computational methods.

All DFT calculations were carried out using Gaussian 09 program. In the gas phase, all geometry optimizations were performed with the B3LYP functional¹ using the def2-SVP basis set² for all atoms. The vibrational frequencies were computed at the same level of theory as for the geometry optimizations to confirm whether each optimized structure is an energy minimum or a transition state, and to evaluate the zero-point vibrational energy (ZPVE) and thermal corrections. The single-point energies and solvent effects were computed with the M06-2X³ functional using the def2-TZVP basis set² for all atoms, based on the gas-phase optimized structures. The solvation energies were evaluated by a self-consistent reaction field (SCRF) using the SMD implicit solvent model.⁴

The global reactivity index (GRI) values were also calculated using B3LYP functional and the def2-SVP basis set for all atoms. The ω (electrophilicity index)⁵ values were calculated according to eq 1. In eq 1, the μ (electronic chemical potential)

value could be obtained by $\mu = (\mathcal{E}_{\text{HOMO}} + \mathcal{E}_{\text{LUMO}})/2$ and the η (chemical hardness) value could be obtained by $\eta = \mathcal{E}_{\text{HOMO}} - \mathcal{E}_{\text{LUMO}}$.⁶

$$\omega = (\mu)^2/2\eta \quad (1)$$

$$N = \mathcal{E}_{\text{HOMO}}(\text{Nu}) - \mathcal{E}_{\text{HOMO}}(\text{TCE}) \quad (2)$$

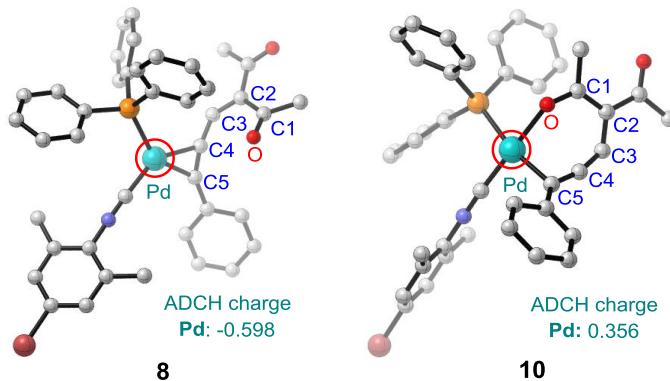

The $\mathcal{E}_{\text{HOMO}}$ values refer to the orbital energies of the highest occupied molecular orbital (HOMO), and the corresponding orbital and the $\mathcal{E}_{\text{LOMO}}$ values refer to the orbital energies of the lowest unoccupied molecular orbital (LUMO). The N (nucleophilicity index)⁷ values were calculated with eq 2. In eq 2, tetracyanoethylene (TCE) with the lowest HOMO energy among the organic molecules serves as a reference.⁸

The ω_k (local electrophilicity) values were calculated according to eq 3.⁹ In eq 3, the f_k^+ (Fukui function) value could be obtained by $f_k^+ = q_k(N+1) - q_k(N)$.¹⁰

$$\omega_k = \omega \cdot f_k^+ \quad (3)$$

3. The critical electronic and geometric information for intermediate 8, 10, and transition state 9-ts.

Table S1. Optimized geometries for intermediate 8 and 10. Bond lengths are given in angstroms.

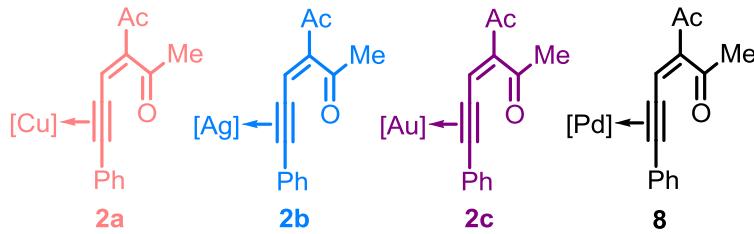

Complex	8	9-ts	10
Pd-O	4.07	2.34	2.19

¹The electronic energy calculated by B3LYP in gas phase. ²The thermal correction to enthalpy calculated by B3LYP in gas phase. ³The thermal correction to Gibbs free energy calculated by B3LYP in gas phase. ⁴The electronic energy calculated by M06-2X in tetrahydrofuran or dichloromethane solvent. ⁵The B3LYP calculated imaginary frequencies for the transition states.

6. Free-energy profiles for coinage-metals-catalyzed cyclization of enynones.

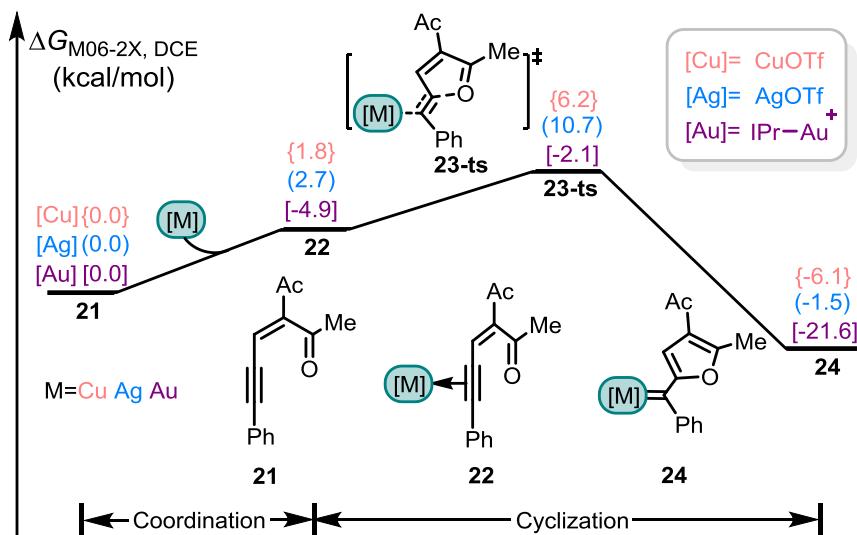

Figure S1. Free-energy profiles for the CuOTf, AgOTf, or IPr-Au^{+(I)}-catalyzed cyclization of enynone to afford metal carbene complexes. The energies are in kcal/mol and represent the relative free energies, which were calculated using the M06-2X/def2-TZVP//B3LYP/def2-SVP method in dichloromethane solvent.

CuOTf(I), AgOTf(I), or IPrAu^{+(I)} were used as active catalysts,¹¹ enynone **21** can be activated by the coordination in corresponding complex **22**. An intramolecular nucleophilic attack via five membered ring type transition state **23-ts** leads to the formation of furanyl-carbene intermediates **24**. DFT calculations found that the activation free energy for this step is only 6.2, 10.7, or -2.1 kcal/mol, when Cu(I), Ag(I), or Au(I) was used respectively.

7. Free-energy profiles for transition-metals-mediated cyclization of enynones.

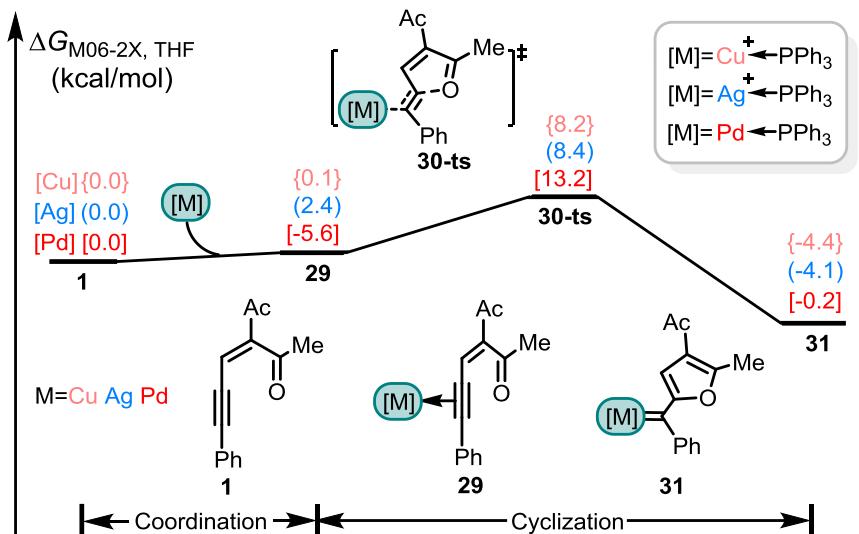

Figure S2. Free-energy profiles for the Cu, Ag, or Pd-mediated cyclization of enynones to afford metal carbene complexes. The energies are in kcal/mol and represent the relative free energies, which were calculated using the M06-2X/def2-TZVP//B3LYP/def2-SVP method in tetrahydrofuran solvent.

As shown in Figure S2, we calculated the free energy profiles for the cyclization process by using Cu, Ag or Pd with PPh_3 ligand. The coordination of enynone **1** onto Cu, Ag or Pd forms corresponding complex **29**. Subsequently, an intramolecular nucleophilic attack would take place via a five-membered ring-type transition state **30-ts** to afford the furan metal-carbene intermediate **31**. The calculated free energy barrier for this step is 8.2 or 8.4 kcal/mol, when Cu or Ag was used. However, the free energy barrier for this step with Pd was as high as 13.2 kcal/mol, which was evidently higher than that with coinage metals. This free-energy profiles reveals that the ligand cannot affect the reactivity in direct cyclization pathway.

8. Free-energy profiles for Pd-catalyzed enynones and isocyanide to ketenimine.

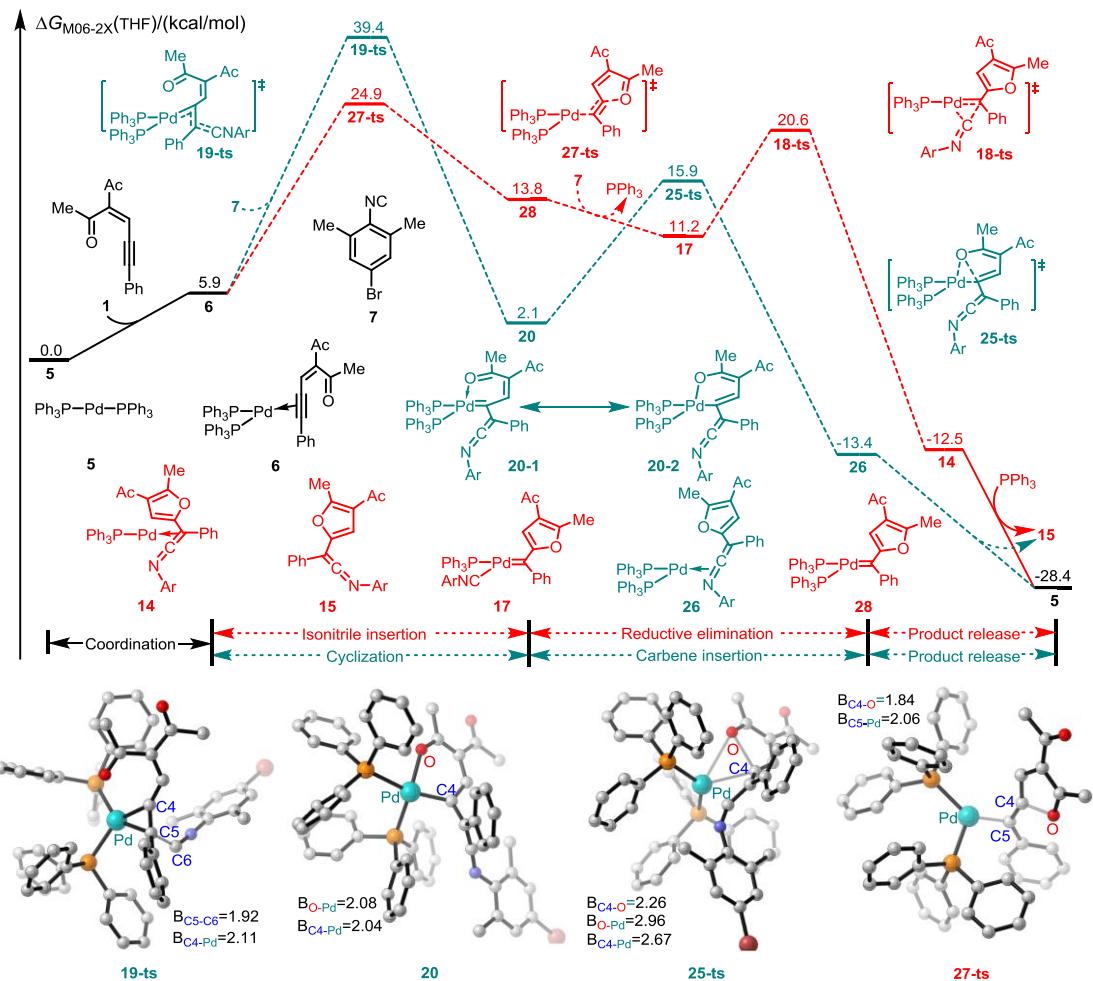

Figure S3. Gibbs energy profiles for Pd-catalyzed enynones and isocyanide. Values are given in kcal/mol and represent the relative free energies calculated by using the M06-2X/def2-TZVP//B3LYP/def2-SVP method in tetrahydrofuran solvent. Optimized geometries of transition states **19-ts**, **25-ts**, **27-ts** and intermediate **20**. Bond lengths are given in angstroms.

The coordination of enynone **1** onto Pd forms complex **6** with endergonic 5.9 kcal/mol. Subsequent an intramolecular nucleophilic attack would take place via transition state **19-ts** with an energy barrier of 33.5 kcal/mol to afford six-membered palladacycle **20**, with a free energy release of 3.8 kcal/mol. In geometry of that intermediate, the bond lengths of Pd-O and Pd-C4 are 2.08 and 2.04 Å, which can be considered as two resonance structures of Pd(0)-carbene **20-1** and Pd(II)-vinyl **20-2**. The following allylic reductive elimination can occur via transition states **25-ts** to irreversibly afford a ketenimine-coordinated Pd(0) complex **26**. After ligand dissociation, active species **5** can be regenerated with the release of furanyl ketenimine

product **15**. Alternatively, an intramolecular nucleophilic attack would take place via transition state **27-ts** to afford furan ring in Pd-carbene intermediate **28** with a free energy barrier of only 19.0 kcal/mol, which is much higher than the metal of copper, silver and gold in Figure 1. Then the Pd-carbene intermediate **28** can react with enynone through ligand exchange to afford complex **17** with exothermic 2.6 kcal/mol. The Subsequent migratory insertion could occur via a three-membered ring concerted transition state **18-ts** with an energy barrier of only 9.4 kcal/mol to form intermediate **14**, which undergoes the ligand exchange with phosphine to obtain furanyl ketenimine product **15** with the regeneration of active species **5**.

9. Details about the electronic properties of intermediate **12**.

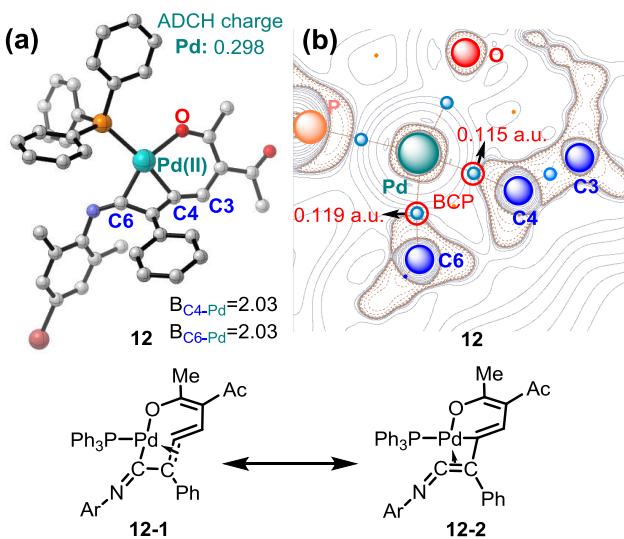

Figure S4. (a) Optimized structure of intermediate **12**. (b) Laplacian plots of electron density for intermediate **12** on the C4-Pd-C6 plane.

We gave the critical atomic charge and geometric information for the intermediate **12** in Figure S4 (a). The bond lengths of Pd-C6 and Pd-C4 are 2.03 and 2.03 Å. Moreover, the ADCH charge and localized orbital bonding analysis (LOBA) determine that the oxidation state of Pd is +2. To further investigate the two resonance structures of intermediate **12**, the Laplacians of the electron density on the plane defined by Pd, C4 and C6 of intermediate **12** were plotted using Atoms-in-Molecules (AIM) analysis. As shown in Figure S4 (b), the electron densities at the BCPs (bond critical points) of

Pd-C6 and Pd-C4 bond were calculated to 0.119 a.u. and 0.115 a.u.. It indicates that the bond strengths of those two bonds are close, therefore, both of resonance structures **12-1** and **12-2** contribute to this intermediate.
