Experimental Details

Materials and Instrumentation

All NMR data processing were carried out with MestReNova software (version 11.0.0, Mestrelab Research S.L., A Coruña, Spain). Chemical shifts for ^1H -NMR, ^{13}C -NMR were reported relative to residual protiated solvent acetonitrile- d_3 (Cambridge Isotope Laboratories, Inc., CD_3CN , 99.8%) at $\delta = 1.940$ ppm, quintet. The chemical shifts for ^{11}B -NMR are referenced relative to $\text{BF}_3 \cdot \text{Et}_2\text{O}$ at $\delta = 0$ and ^{19}F -NMR chemical shifts are referenced to CFCl_3 at $\delta = 0$ as external reference. Coupling constants (J) are given in Hz. Multiplicities of signals are indicated by the following abbreviations: s (singlet), d (doublet), t (triplet), q (quartet), dd (doublet of doublets), m (multiplet) and b (broad). High resolution mass spectra were measured using an Agilent 6550 i-Funnel system. Chromatography experiments were performed on Agilent 1260 Infinity HPLC system equipped with Raptor C18 column (100×3 mm; $2.7 \mu\text{m}$ particle size) using water/acetonitrile 1/9 mixture as eluent (0.3 mL min^{-1}) and compared to the solvent blank run. Diode Array Detector (1260 DAD VL+) was fixed in the spectral region of interest at 630 nm. UV-visible absorption spectra were performed on a Shimadzu Spectrophotometer UV-1800 (Shimadzu Corporation, Japan) reference cell and the other as a sample cell in the dual-beam UV-Vis system. 2D and 3D fluorescence excitation/emission spectra were obtained from a Shimadzu RF-6000 Fluorescence Spectrometer (Shimadzu Corporation, Japan), which was equipped with a 150 Watt Xenon lamp and controlled by LabSolutions RF software (Shimadzu Corporation, Japan). Peak deconvolution to Gaussian bands was performed using PeakFit™ program (version. 4.12, Systat Software, Inc., U.S.).

X-Ray Crystallography

All crystallography measurements were performed using in-house facilities at Newcastle University. Crystal structure data which were collected in-house used an Xcalibur, Atlas, Gemini ultra-diffractometer equipped with a sealed X-ray tube ($\lambda \text{ CuK}\alpha = 1.54184\text{\AA}$) and a CryostreamPlus open-flow N_2 cooling system (Oxford Cryosystems Ltd, UK). Software CrysAlisPro (Version 1.171.37.35, Agilent Technologies, U.S.) was used for cell refinement, data collection, data reduction and intensities correction for absorption.

Synthesis

Preparation of **BD**

BD was synthesised by a modified reported literature method.¹ Pyrrole-2-carboxaldehyde (770.3 mg, 8.1 mmol, 1 e.q.) was dissolved in dry DCM (39 mL) and cooled down to -3 °C under a nitrogen atmosphere. 3-ethyl-2,4-dimethyl-1H-pyrrole (1.1 mL, 8.1 mmol, 1 e.q.) was added to the reaction mixture which was stirred for 10 mins, followed by slow addition of POCl₃ (0.76 mL, 8.1 mmol, 1 e.q.). The reaction mixture was stirred for 3h during which time the temperature was left to rise from -3 °C to R.T. The reaction mixture turned from pale orange to dark orange. Once the starting materials were consumed as followed by TLC, Et₃N (6.7 mL, 48.6 mmol, 6 e.q.) and after 5 mins BF₃.OEt₂ (6 mL, 48.6 mmol, 6 e.q.) were added sequentially to an ice-cold reaction mixture. The resulting solution was stirred for 1.5 h as the solution was left to equilibrate from 0 °C to R.T. The reaction mixture became dark brown. The reaction was washed three times with sat. NaHCO₃ and H₂O (50 mL) sequentially. The separated organic layer was concentrated and passed through a silica plug using pure DCM to remove most of the impurities. The crude product was further purified by silica gel column chromatography (eluent: DCM: petroleum ether, 20-60%, v/v) to afford the final product **BD** as a pale yellow solid with a strong green fluorescence. (1.1 g, 4.4 mmol, 55% yield); ¹H NMR (300 MHz, Chloroform-*d*) δ (ppm) = 7.60 (d, 1H), 7.15 (s, 1H), 6.89 (d, *J* = 2.8 Hz, 1H), 6.42 (dd, *J*₁ = 3.9 Hz, *J*₂ = 2.1 Hz, 1H), 2.60 (s, 3H), 2.43 (q, *J* = 7.6 Hz, 2H), 2.21 (s, 3H), 1.11 (t, *J* = 7.6 Hz, 3H). ¹³C NMR (75 MHz, Chloroform-*d*) δ (ppm) = 163.44, 141.18, 137.98, 136.32, 134.91, 132.40, 125.36, 123.62, 115.70, 17.39, 14.34, 13.43, 9.59. ¹¹B NMR (96 MHz, Chloroform-*d*) δ (ppm) = 0.60 (t, *J* = 30.9 Hz). ¹⁹F NMR (282 MHz, Chloroform-*d*) δ (ppm) = -146.06 (q, *J* = 31.2 Hz). HRMS (*m/z*): found [M - F]⁺: 229.1340, calcd for C₁₃H₁₅BFN₂: 229.1315

Preparation of a**JBD**

JUL-CHO (92.6 mg, 0.46 mmol, 1.1 e.q.), piperidine (0.415 mL, 4.2 mmol, 10 e.q.) and glacial acetic acid (0.24 mL, 4.2 mmol, 10 e.q.) were added to a solution of **BD** (104 mg, 0.42 mmol, 1 e.q.) in anhydrous CH₃CN (17 mL) containing 4Å dry molecular sieves (1 g). The resulting mixture was refluxed under nitrogen for 2.5 hours and monitored by TLC until the complete consumption of the starting material. The colour changed from dark brown to dark blue. The molecular sieves were removed by a sinter funnel and washed with DCM till

colourless. All the collected DCM and original CH₃CN solutions were removed by a rotary evaporator. The crude product was redissolved in Et₂O: hexane (1:1) and purified by preparative alumina TLC (eluent: Et₂O: hexane, 1:1) to give the pure product **aJBD** as a black solid with a metallic green colour. (58 mg, 0.13 mmol, 32% yield); ¹H NMR (400 MHz, Chloroform-*d*) δ (ppm) = 7.56 (m, 1H), 7.43 (apparent tr, *J* = 17 Hz 2H, *trans* CH=CH), 7.10 (s, 2H, -CH-phenylJUL), 6.98 (s, 1H), 6.77 (d, *J* = 2.8 Hz, 1H), 6.38 (dd, *J*₁ = 3.8 Hz, *J*₂ = 2.1 Hz, 1H), 3.26 (t, *J* = 5.8 Hz, 4H, -CH₂-JUL), 2.76 (t, *J* = 5.8 Hz, 4H, -CH₂-JUL), 2.68 (q, *J* = 7.5 Hz, 2H), 2.18 (s, 3H), 1.97 (m, 4H, -CH₂-JUL), 1.22 (t, *J* = 7.5 Hz, 3H). ¹³C NMR (101 MHz, Chloroform-*d*) δ (ppm) = 158.78, 145.08, 142.09, 140.85, 137.93, 135.74, 135.08, 132.81, 127.69, 123.73, 122.60, 121.33, 119.35, 115.05, 113.18, 50.15, 27.80, 21.73, 19.10, 13.79, 9.27. ¹¹B NMR (96 MHz, Chloroform-*d*) δ (ppm) = 1.03 (t, *J* = 32.6 Hz). ¹⁹F NMR (282 MHz, Chloroform-*d*) δ (ppm) = -143.00 (q, *J* = 32.1 Hz). The measured molar extinction coefficient at 648 nm for **aJBD** in DMSO is 58,000 M⁻¹ cm⁻¹. HRMS (m/z): found [M + H]⁺: 432.2446, calcd for C₂₆H₂₉BF₂N₃: 432.2427; HPLC (min): 8.877.

Quantum Yield and Solution Fluorescence Lifetime Measurements

For fluorescence quantum yields (Φ_{FLU}) measurements in different solutions, were measured using the relative quantum yield method with respect to the reference dye Cy643. All the samples and the reference were prepared freshly in appropriate solvents on the day of use. The optical density (OD) of the UV absorbance was less than 0.05 at the excitation wavelength. Fluorescence areas were calculated by the instrument software (LabSolutions RF software) using the corresponding fluorescence spectra. Quantum yields were corrected for changes in refractive index of the solvents. Solution fluorescence lifetime measurements for **aJBD** were recorded by an upright confocal microscope which comprised of a SPC-150 TCSPC module (Becker & Hickl, Berlin, Germany).

Time Resolved Transient Absorption Spectroscopy

Excited state dynamic processes of **aJBD** in femtosecond to nanosecond time scales were performed by transient absorption spectroscopy. A 590 nm pump pulse (100 fs fwhm) was applied to excite the **aJBD** complex. The sample solution was prepared in two different solvents (hexane and DMSO) with an optical density between 0.2-0.8 in a 2 mm cuvette. The data were globally fitted to get the relaxation time constants and the associated decay component spectra. Also, steady-state absorption spectra were measured before and after the

pump-probe measurement to make sure that the sample did not change during the measurement.

Preparation of Giant Unilamellar Vesicles (GUVs)

GUVs were prepared by the electroformation method. The whole apparatus for preparing GUVs was precleaned with EtOH in a bath sonicator for 30 min, and dried under nitrogen carefully to remove all the house dust which would impact on the GUVs growing. The test chamber was assembled with one piece of coverslip at the bottom with two platinum wires suspended on it. The lipid solution of 1-palmitoyl-2-oleoyl-sn-glycero-3-phosphocholine (POPC) was prepared in a CHCl₃: MeOH (2: 1, v/v) mixture. An appropriate mixture of POPC lipid (4 μL on each wire) was deposited onto two parallel platinum wires respectively, and the solvent was evaporated for 30 mins till completely dry. Sucrose solution (300 mM, 2 mL) was added into the assembled chamber. The chamber was subjected to an alternating current (AC) frequency of 10 Hz with an output voltage of 3.3 Vpp at 50 °C for 1.5 hours. GUVs were stained with **aJBD** (2 μL, 50 μM) in the testing chamber prior to the microscopy measurements.

GUVs Fluorescence Lifetime Imaging

The presence of GUVs in solutions were firstly checked by confocal microscopy, and FLIM measurements were performed on a modified Nikon Eclipse Ti-U inverted microscope (Nikon Instruments Inc., Melville, NY, USA) at the Rutherford Appleton Laboratory. Laser light was focused through a 60 x water immersion plan-apochromat objective with a numerical aperture of 1.2. The GUVs were imaged while samples were excited at 633 nm with an acousto-optic tuneable filters (AOTF) coupled with a fianium supercontinuum light source (Fianium, NKT Photonics, Southampton, UK), which was tuneable (400-2000 nm) and produced 40 ps laser pulses at 40 MHz (25 ns between laser pulses). In the one-photon laser scanning, 256 × 256 pixels/decay curves were used. Fluorescence lifetime images were obtained using the SPCImage analysis software (version 9.80, Becker & Hickl GmbH, Germany) using the SPC-150 mode. The decay trace for each pixel with a pixel bin of 10 was best fit to a single or double exponential model to allow analysis in the nanosecond decay domain. The quality of a goodness-of-fit was judged by the chi-squared value (χ^2).

For the ramping voltage experiment, the applied voltage was gradually increased from 0 mV to 100 mV, 200 mV, 300 mV then back to 0 mV followed by lifetime measurements at the same time. Each fluorescence lifetime image was collected for 20 sec. For the ON-OFF cycles GUVs were depolarized for 5 seconds with 250 mVpp voltage. A GUV was subjected to “on-off” direct current (DC) pulse for 50 “on-off” cycles after depolarization. Each cycle included 20 seconds with voltage applied (600 mVpp) which was called “on” and 20 seconds for the resting state (0 mVpp) which was called “off”. A fluorescence lifetime image was collected for 20 seconds during each “on” or “off” process.

^a Absorption and emission ($\lambda_{\text{ex}} = 590$ nm) maxima data obtained from experimental measurements from the instruments. ^b Data are the quantum yields measured relative to **Cy643** in MeOH. ($\Phi_{\text{Cy643}} = 43\%$). To convert wavelength to wavenumber, the following formula was used: $\tilde{\nu} = 1/\lambda$; $\tilde{\nu}$ is wavenumber (cm^{-1}) and λ is wavelength (nm). The Stokes' shift (SS) was calculated by $\lambda_{\text{abs}} - \lambda_{\text{em}}$ in wavenumbers (cm^{-1}).
