IR and UV-Vis Spectra and magnetic moment

The characteristic imines (C=N) stretching vibration of the synthesized complexes were located within the range 1580-1621 cm⁻¹.¹Dicyanamide complexes displayed strong bands at ~ 2327 cm⁻¹ and 2298 cm⁻¹ in complex **1**; 2346 cm⁻¹ and 2266 cm⁻¹ in complex **2**.² Such spectral values are due to the bridging mode of v(dca). The IR spectra were extensively compared with previously reported Zn (II)-complexes concerning the bridging mode of dicyanamide co-ligands.³⁻⁵The electronic spectra of both complexes show bands at ~270 and ~370 nm, which may be assigned as π→π* and n→π* transitions, respectively.⁶ The absence

of any d-d transition is in accordance with the presence of d^{10} configuration of zinc(II).⁷

Room temperature magnetic susceptibility measurements show that both complexes are diamagnetic, as anticipated for zinc(II) complexes.

Hirshfeld analysis

Hirshfeld surface study⁸⁻¹⁰ leads us to understand the different intermolecular interactions that were carried out for both complexes **1** and **2** with the help of Crystal Explorer software.¹¹ Two-dimensional fingerprint plots¹²⁻¹⁴ were obtained and two types of distances (d_e and d_i) are obtained for each point on the Hirshfeldisosurface. d_e is defined as the distance between the surface and the nearest nucleus external to the surface whereas d_i is just the opposite of d_e i.e. the distance between the surface and the nearest nucleus internal to the surface. Another three dimensional term (d_{norm}) is also important as far as Hirshfeld surface analysis is concerned. It is nothing but a normalized contact distance. d_e and d_i are normalised by the van der Waals radius of the atom (r_i^{vdW} and r_e^{vdW}) and the summation of these two quantities result in normalized contact distance (d_{norm}) according to the following equation:

$$d_{norm} = \frac{(d_i - r_i^{vdW})}{r_i^{vdW}} + \frac{(d_e - r_e^{vdW})}{r_e^{vdW}}$$

Three types of Hirshfeld surfaces of the complex were achieved on mapping over d_{norm} , curvedness and shape index (Figure S1). Curvedness is actually a function of the root mean square of the curvature of the surface and thus defining the shape of the crystal. On the other hand shape index is a qualitative measurement of the shape and very sensitive to a slight change in the shape of the surface, particularly in a region where the curvedness is

very low. Figure **S2** clearly depicts three types of regions i.e. red, blue and white which are defined by d_{norm} values.

On analyzing the 2D Fingerprint plots (Figure **S2**), it is found that the proportion of the Hirshfeld surface for C···H interaction in **1** (34.8%) is considerably higher than that in **2** (24.4%). The Hirshfeld surface proportion of H···N/N···H interaction is, on the other hand, is comparable (25.8% for complex **1** and 25.3% for complex **2**). The O···H/H···O interaction is around 4.3% for complex **1** which is also slightly greater than that for complex **2** (3.2%).
