D Optics

D.1 Theory

To study the optical properties, the frequency-dependent dielectric matrix in the long wavelength limit ($q \rightarrow 0$) can be calculated using the sum over states approach.¹ The formula for the imaginary part of the dielectric constant is a 3x3 Cartesian tensor

$$\epsilon_2^{\alpha\beta}(\omega) = \frac{4\pi^2 e^2}{\Omega} \lim_{q \rightarrow 0} \frac{1}{q^2} \sum_{c,v,k} 2\omega_k \delta(\epsilon_{ck} - \epsilon_{vk} - \omega) \times \langle u_{ck+e_\alpha q} | u_{vk} \rangle \langle u_{ck+e_\beta q} | u_{vk} \rangle^* \quad (1)$$

where the indices c and v correspond to the conduction and valence band states, respectively and u_{ck} is the periodic part of the orbitals at the k -point κ . The vector e_α are unit vectors for the three Cartesian directions. α and β refer to axis x, y, z . The real part of the dielectric constant tensor can be derived from the imaginary part using Kramers-Kronig relations:

$$\epsilon_1^{\alpha\beta}(\omega) = 1 + \frac{2}{\pi} P \int_0^\infty \frac{\epsilon_2^{\alpha\beta}(\omega') \omega'}{\omega'^2 - \omega^2} d\omega' \quad (2)$$

where P denotes the principal value. The real part of the optical conductivity ($\sigma(\omega)$) is defined as

$$\sigma_1(\omega) = Re[\sigma(\omega)] = \frac{\omega}{4\pi} \epsilon_2(\omega) \quad (3)$$

where $\sigma(\omega)$ and ω are in the cgs unit of sec^{-1} . The cgs conductivity is 9×10^{11} times larger than the SI conductivity unit (Siemens/cm) which in the form of $\sigma_1(\omega) = \frac{\varepsilon_2(\omega) \cdot \omega}{60}$ where ω is in the unit of cm^{-1} . The corresponding imaginary part of $\sigma(\omega)$ in SI unit is ²

$$\sigma_2(\omega) = -\frac{\omega(\varepsilon_1(\omega) - 1)}{60} \quad (4)$$

The complex dielectric constant can be expressed as:

$$\varepsilon(\omega) = \varepsilon_1(\omega) + i\varepsilon_2(\omega) = \frac{4\pi i}{\omega} \sigma(\omega) = (\tilde{n} + ik)^2 \quad (5)$$

where \tilde{n} and k are the index of refraction and the extinction coefficient respectively, and can be evaluated by the calculated dielectric constants from equations (1) and (2).

$$\tilde{n} = \frac{1}{\sqrt{2}} (\varepsilon_1 + (\varepsilon_1^2 + \varepsilon_2^2)^{\frac{1}{2}})^{\frac{1}{2}} \quad (6)$$

$$\tilde{k} = \frac{1}{\sqrt{2}} (-\varepsilon_1 + (\varepsilon_1^2 + \varepsilon_2^2)^{\frac{1}{2}})^{\frac{1}{2}} \quad (7)$$

In the case of normal incidence, the reflectivity R and the absorption coefficient α (sec^{-1} in cgs unit) in terms of \tilde{n} and k are defined as ²

$$R = \frac{(\tilde{n} - 1)^2 + k^2}{(\tilde{n} + 1)^2 + k^2} \quad (8)$$

$$\alpha = \frac{2\omega k}{c} \quad (9)$$

In SI unit, ω and α are in cm^{-1} , $\alpha = 4\pi\omega k$. In all cases, both the low frequency region $\omega\tau \ll 1$ (τ is the relaxation time) and the high frequency region $\omega\tau \gg 1$ are extensively studied to analyze the exact ground state of the material as these two regions carry the signatures of two distinct mechanisms associated with optical conductivity within a solid. While the low frequency region is dominated by free carriers which are in abundance in a metal, the high frequency region is dominated by inter-band electronic transitions typical of a dielectric material. As in the limit $\omega\tau \ll 1$, both \tilde{n} and k become sufficiently large, for example, in a metallic conductor,

$$R = 1 - \frac{2}{\tilde{n}} \rightarrow 1 \quad (10)$$

which means that the conductor is characterized by its behavior as a perfect reflector with an exceedingly large absorption coefficient in the low frequency region.

D.2 Halogen Comparisons
