### **Table of Content:**

S.1. Impact of protonation at proximal serine in reactivity	S2-S3
Figure S2: DFT optimization of ferrous heme complex	S4
Figure S3: DFT Optimization of iron nitrenoid complex	S4
Figure S4: Results for replica simulation of <b>variant 2</b>	S5
Figure S5: Results for substrate upside-down simulation of <b>variant 2</b>	S6
Figure S6: Testing the enantioselectivity of non-selective <b>variant 1</b>	S7
Figure S7: Results for pro-S hydrogen abstraction and comparison with pro-R hydrogen	S8
Figure S8: QM/MM optimized transition state geometry	S8
Figure S9: Distance correlation plots between ligand and other enzyme residues	S9
Figure S10: QM/MM optimized geometry of cysteine ligated ferrous heme complex	S9
Figure S11: QM/MM PES results of cysteine ligated ferrous heme complex for iron nitrenoid formation	S10
QM coordinates of the CH amination reaction	S11-S18
QM coordinates of the Iron Nitrenoid formation reaction	S18-S22

**S.1. Impact of protonation at proximal serine in reactivity:** The protonation state of the serine was initially considered based on the catalytic cycle described by Arnold and coworkers in their article for intermolecular C-H amination reaction where they have considered it as protonated serine. We, however, performed QM/MM scanning and QM-only DFT study to determine the correct protonation state of proximal serine residue. Our study shows that the protonated serine is more favorable than the deprotonated one both energetically as well as structurally. In the QM/MM study, we have taken the protonated reactant complex (RC) and performed potential energy surface scanning to deprotonate the serine oxygen. During this scanning, we obtained that the energy required to break the O-H bond is high and it climbs up to ~23 kcal/mol. The exact energy barrier is uncertain as the proton starts to interact with the porphyrin nitrogen and distorts the porphyrin arrangement. This was further substantiated by DFT only study. Therefore, a use of deprotonated serine could be doubtful.

It is well known that push-pull effects along the distal and proximal axis of iron regulate the reactivity of heme complex (Denisov et. al). Therefore, protonation (or deprotonation) of the serine could play the same decisive role in the reactivity of P411. In the protonated serine most of the Fe electrons are available along the distal axis (Fe-N) making it more reactive. On the other hand, in the deprotonated serine the iron d-electrons are delocalized along Fe-O linkage making the deprotonated species less reactive. This could also be justified by comparing the Fe-N and Fe-O bond lengths in protonated and deprotonated serine complex. In the deprotonated axial serine, the Fe-O bond length becomes too short and thereby it causes elongation of the Fe-N bond (trans effect). This effect is much less significant when the axial ligand is the protonated serine.

(a) QM/MM scanning

(b) QM-only DFT study

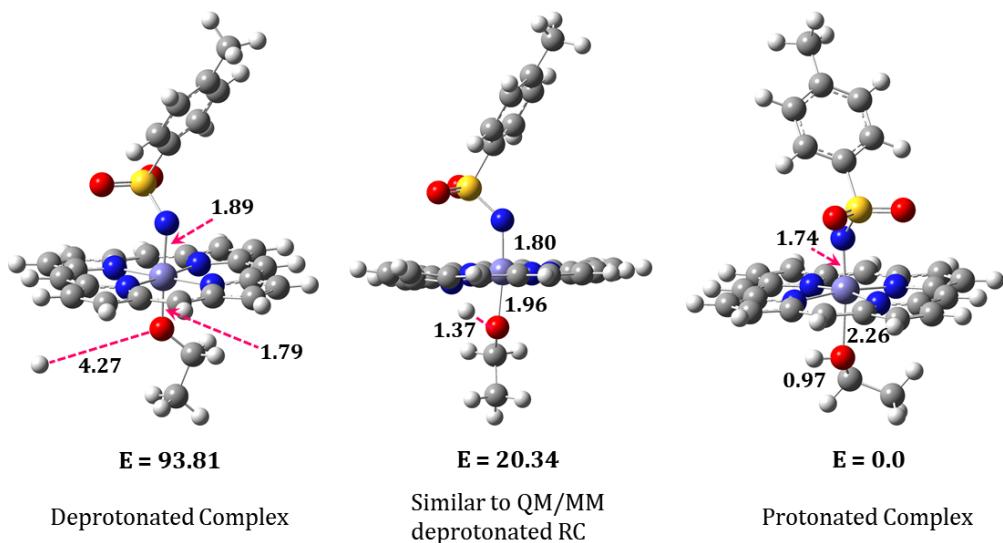

Figure S1: (a) Results of QM/MM potential energy surface scanning that shows two different protonation state of the reactant complex (RC), i.e., protonated, and deprotonated. In deprotonated RC, proton shows the probable interaction with porphyrin nitrogen atom. (b) QM-only DFT studies reveal three distinct geometries, i.e., protonated, completely deprotonated and a geometry similar to the QM/MM deprotonated RC both energetically as well as structurally. Note that distances and energies are given in Å and kcal/mol unit for both results.

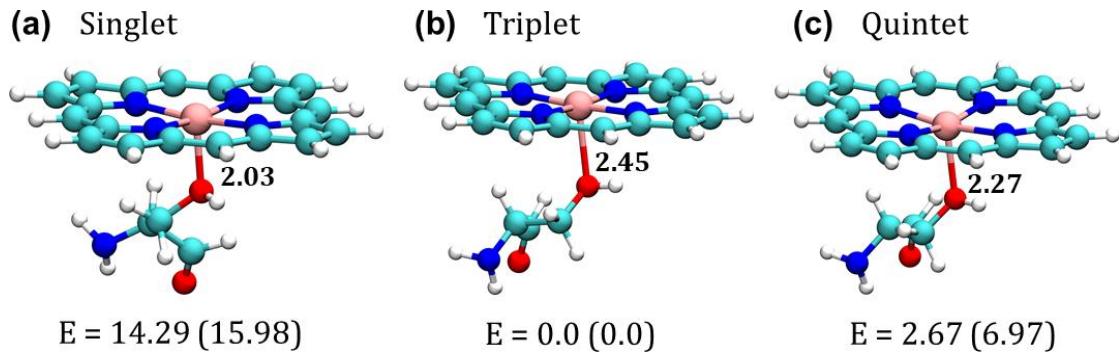

Figure S2: DFT optimization of ferrous heme complex at ground state for three different spin multiplicities. Optimized bond parameters are in Å unit. The relative energies are shown in kcal/mol. The values in parentheses are single-point energies at an extensive basis set (def2-TZVP).

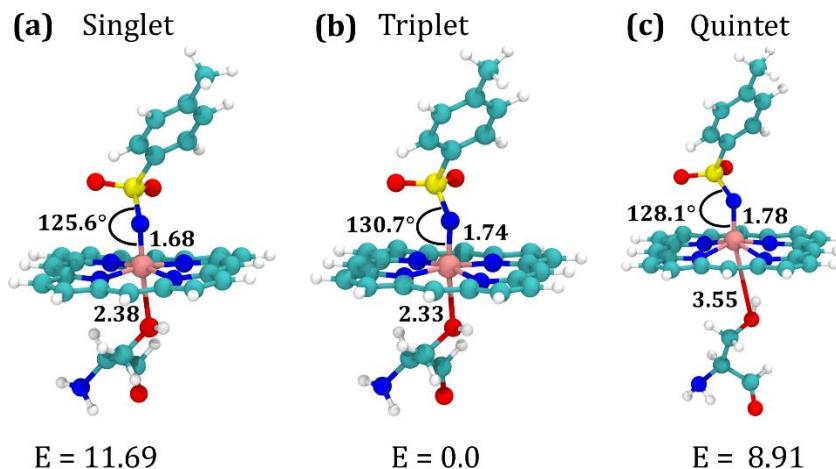

Figure S3: The optimized geometry of iron nitrenoid at different multiplicities. The energy values are evaluated using single-point calculation on optimized geometry using the larger basis set def2-TZVP. All the energies are reported in kcal/mol.

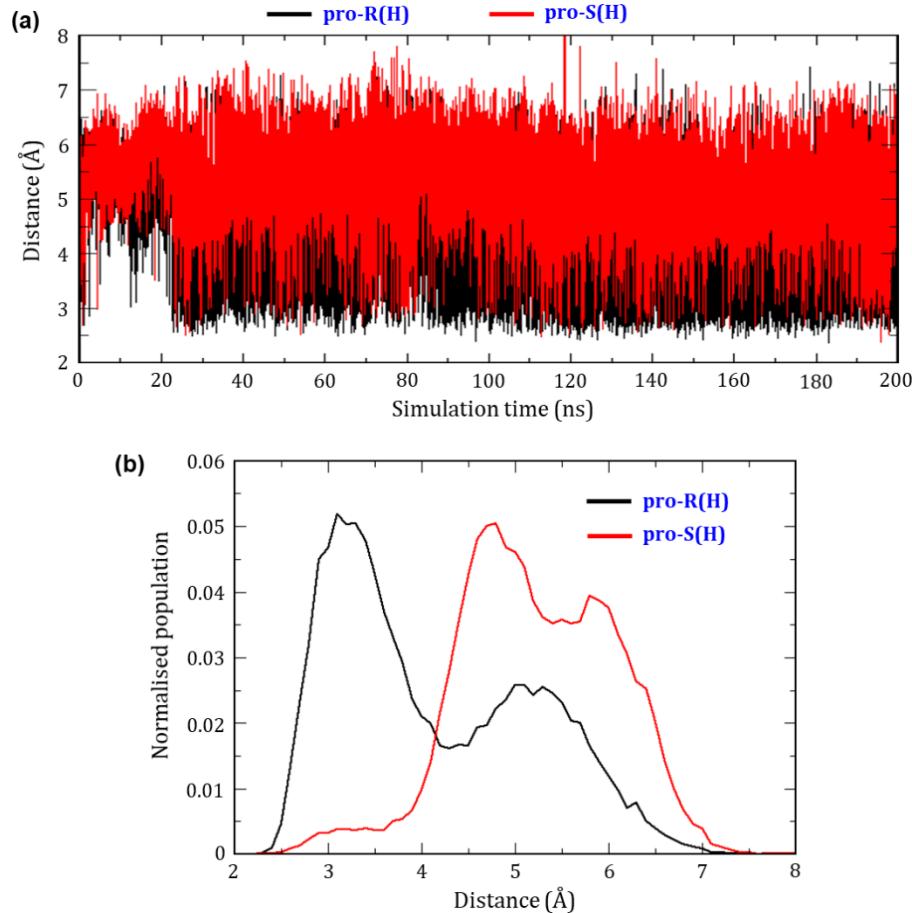

Figure S4: (a) Evolution of distance with time between the pro-R and pro-S hydrogens with the reactive nitrogen (N1) for entire 200 ns replica **variant 2** simulation. (b) The Boltzmann population distribution plot corresponds to distance plots between the pro-R and pro-S hydrogens with the reactive nitrogen (N1) over the entire 200 ns simulation. Note that black and red represent pro-R and pro-S hydrogens for both distance and population distribution plots respectively.

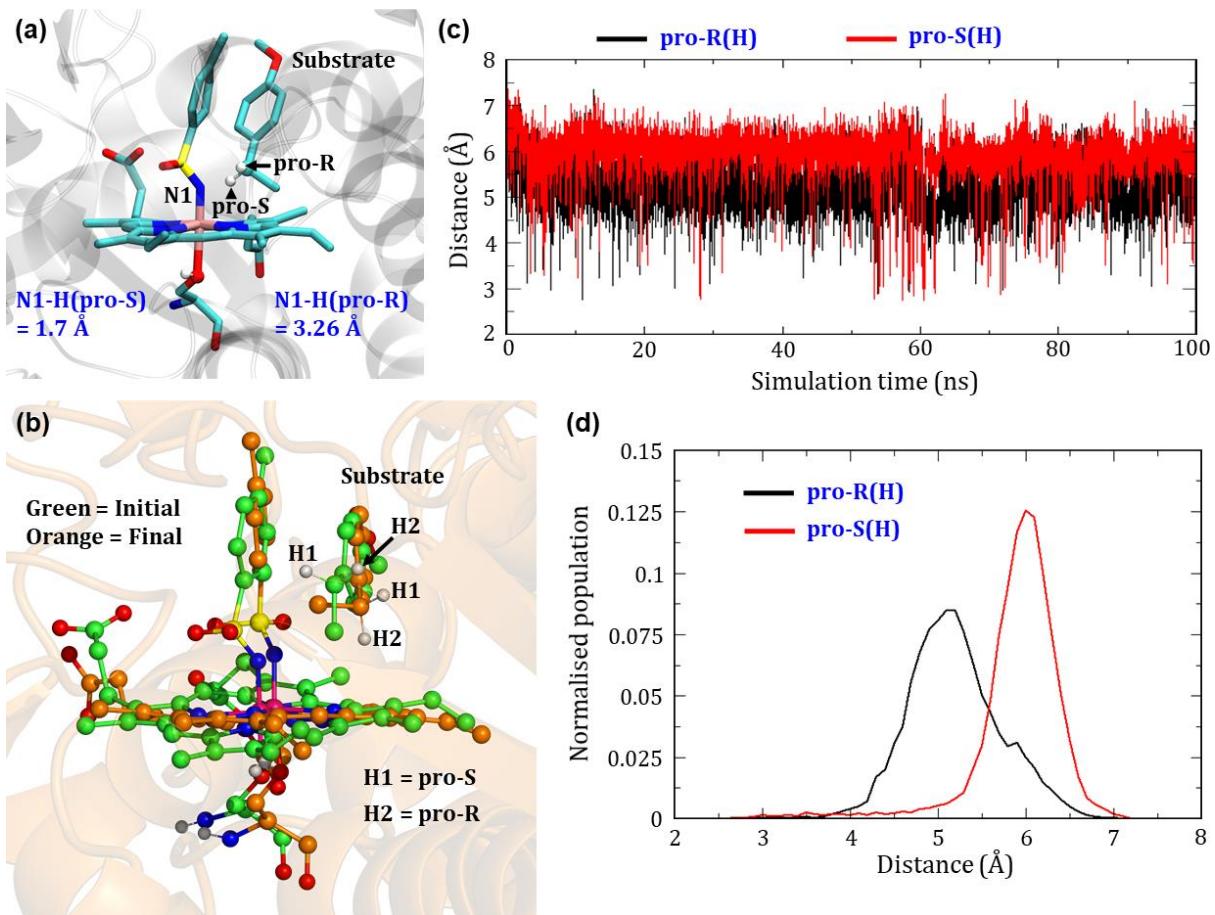

Figure S5: (a) Substrate docked geometry at which the pro-S hydrogen is facing the reactive nitrogen (N1) in **variant 2**. (b) Superimposed image of the snapshots considered from before and after production MD run. Here, green and orange represent the initial and final snapshots. The H1 and H2 hydrogens describe the pro(S) and pro(R) respectively. (c) Distance plots between reactive nitrogen (N1) and pro-R (black) as well as pro-S (red) hydrogens. (d) Boltzmann distribution plot corresponding to the above distance plots with identical color classification.

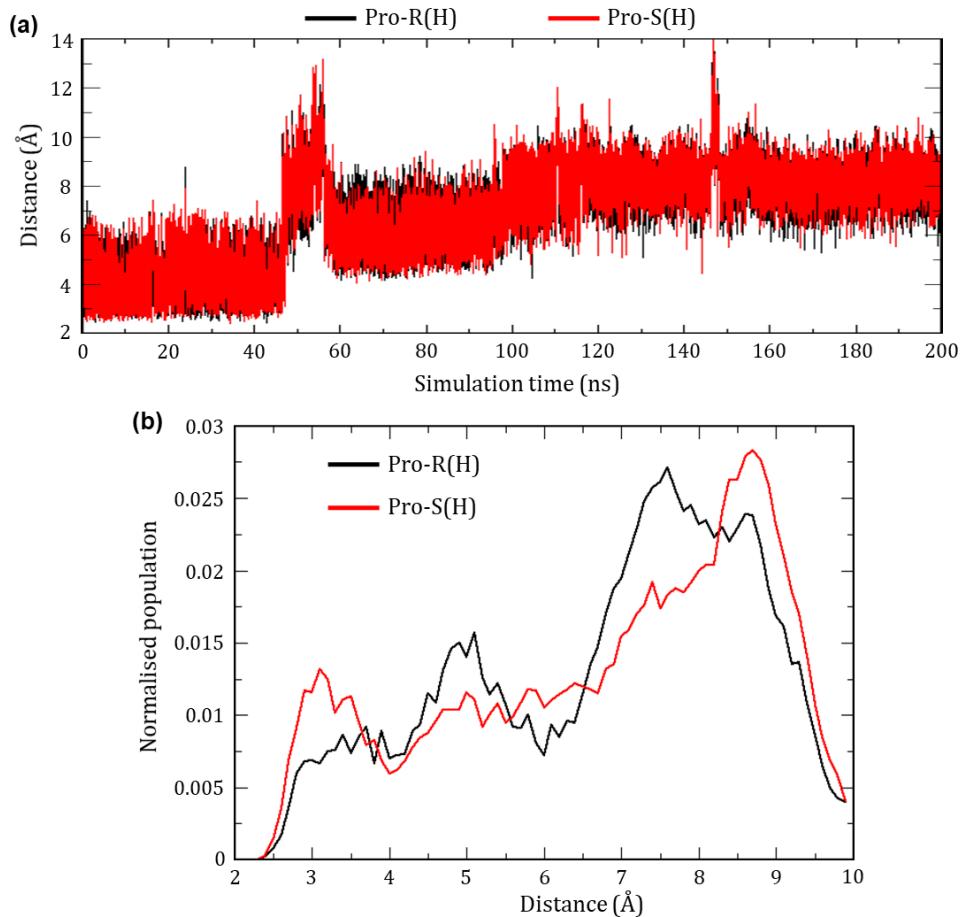

Figure S6: (a) Evolution of distance with time between the pro-R and pro-S hydrogens with the reactive nitrogen (N1) for entire 200 ns replica **variant 1** simulation. (b) The Boltzmann population distribution plot corresponds to distance plots between the pro-R and pro-S hydrogens with the reactive nitrogen (N1) over the entire 200 ns simulation. Note that black and red represent pro-R and pro-S hydrogens for both distance and population distribution plots respectively.

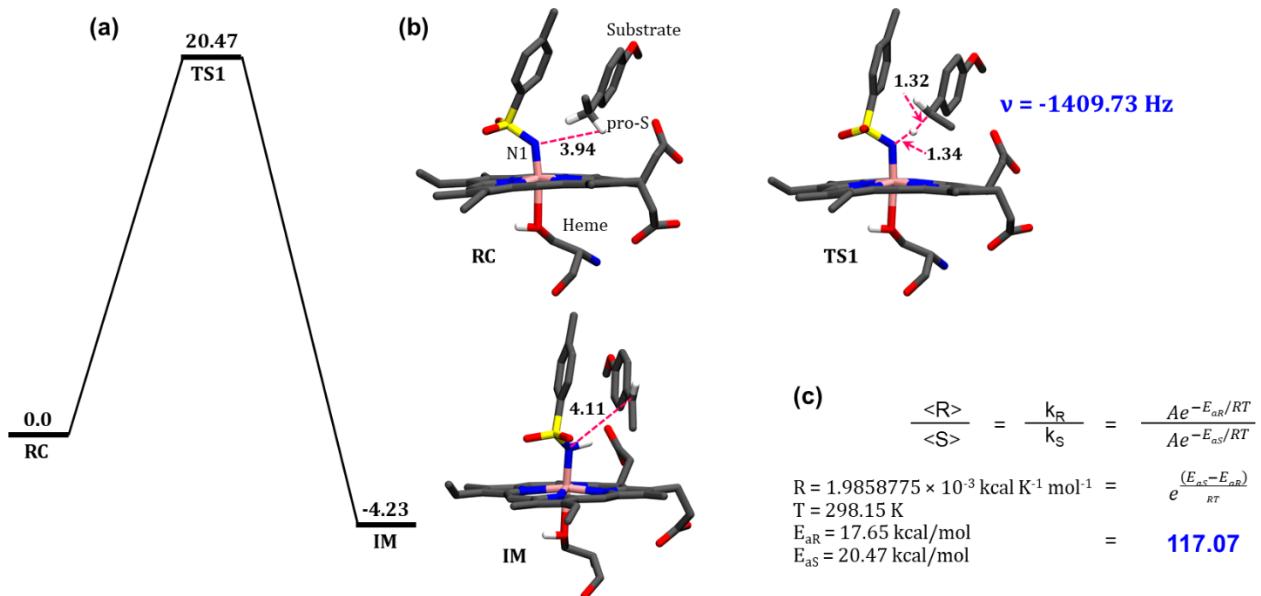

Figure S7: (a) Energy profile diagram for the abstraction of pro-S hydrogen obtained from the PES scanning. Energies are relative to RC and reported in kcal/mol unit. All the energies are Grimme dispersion (GD-3) and ZPE corrected in the same level of theory (ub3lyp/def2-SVP). (b) The key geometries RC, TS, and IM obtained from the PES scanning. All the distances are in Å unit. (c) Arrhenius equation shows the comparative rate constant data.

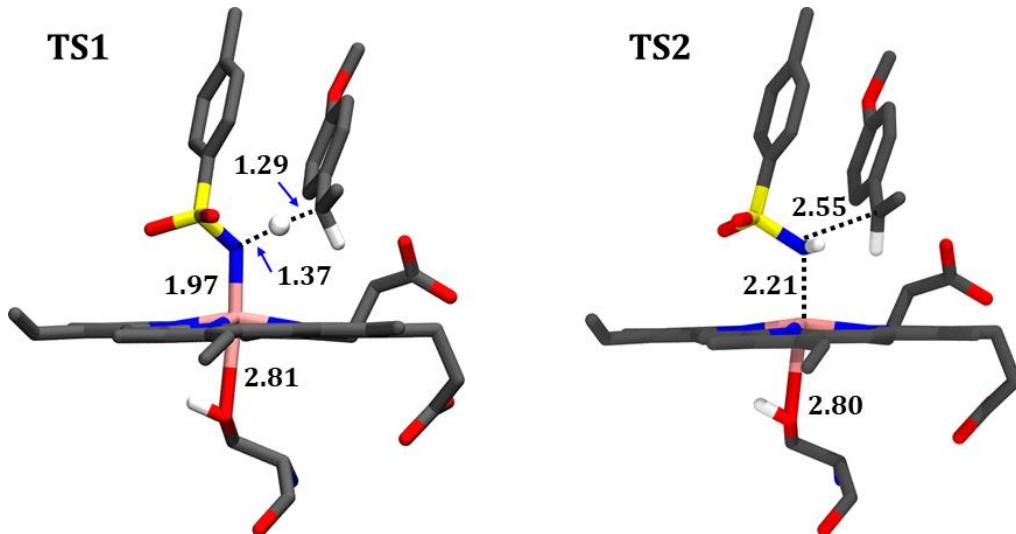

Figure S8: QM/MM optimized transition state geometry for C-H amination reaction; where TS1 and TS2 denote hydrogen abstraction and rebound process, respectively. Bond parameters are in Å unit.

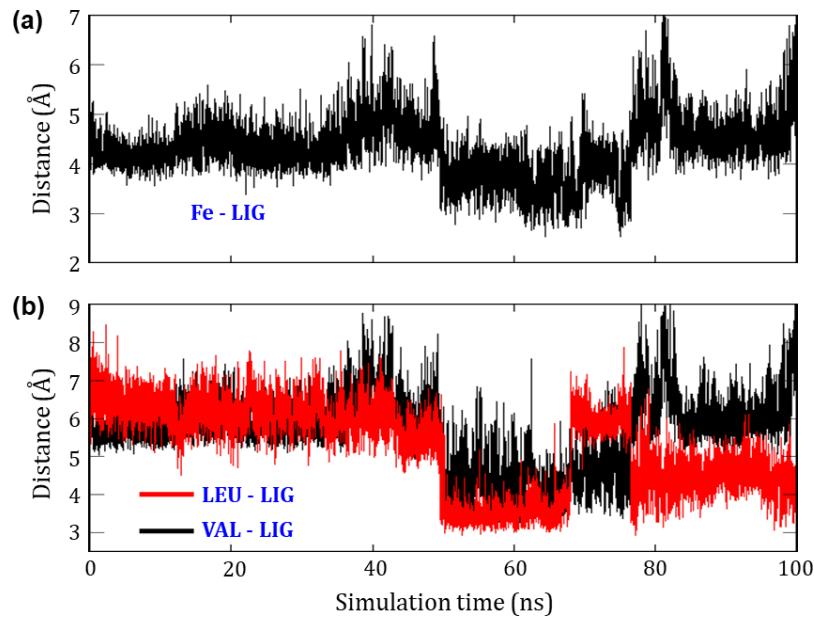

Figure S9: a) The distance between N1 of tosyl azide (TAZ) and Fe of heme porphyrin. (b) Black and red plots show the distance between V328 and L263 with TAZ, respectively.

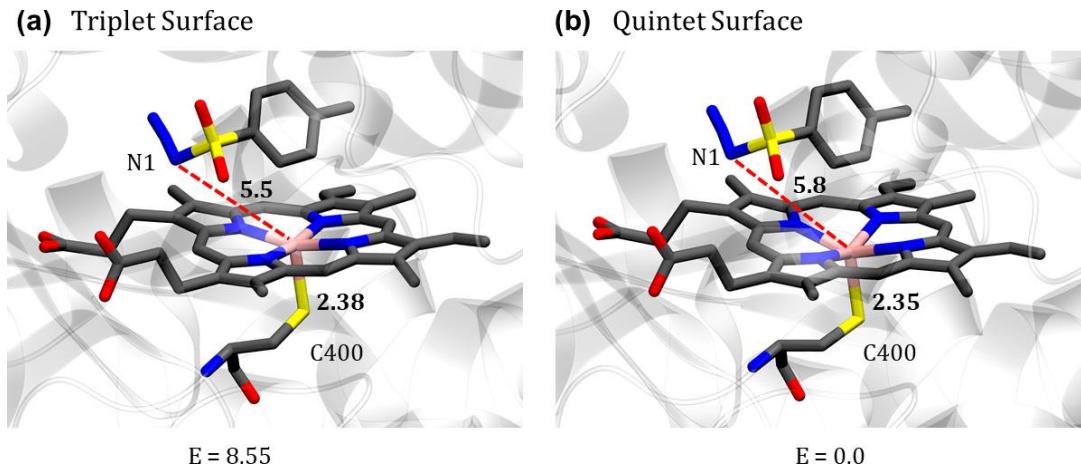

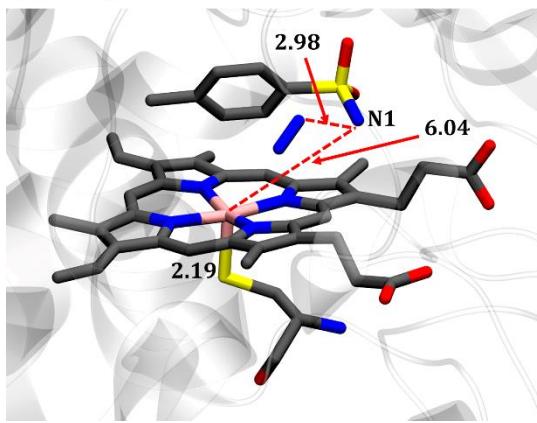

Figure S10: QM/MM optimized geometry of a representative MD snapshot and their relative energy in kcal/mol at (a) Triplet and (b) Quintet surface. The bond parameters are in Å unit.

**(a) Triplet Surface**

**(b) Quintet Surface**

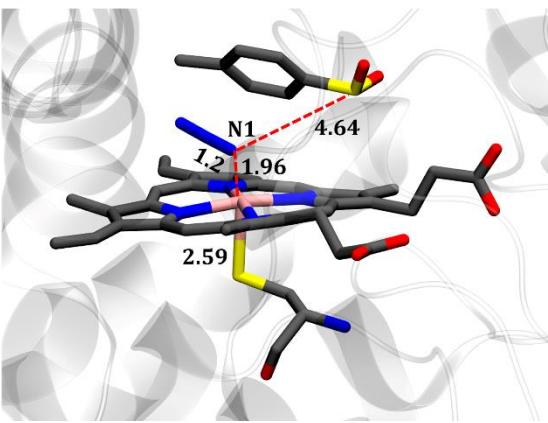

Figure S11: Results for the potential energy surface scanning for the formation of iron nitrenoid in the axial serine to cysteine mutated P411 system. It has been performed in both triplet and quintet surface. Substrate molecule is tosyl azide. All the bond parameters are shown in Å unit.

## Coordinates of atoms in the QM region of the QM/MM calculations for different complex
