## 1. Experimental Section

### 1.1 Reagents and Methods

Unless otherwise described, all reagents and anhydrous solvents used in this work were purchased from commercial sources and used without further purification. D<sub>2</sub>O was purchased from Sigma-Aldrich, and dimethyl sulfoxide (DMSO, 99.7%, Superdry, with molecular sieves, J&K Seal), acetonitrile (MeCN, 99.9%, Superdry, with molecular sieves, J&K Seal) and *N,N*-dimethylformamide (DMF, 99.8%, Superdry, with molecular sieves, J&K Seal) were purchased from J&K Scientific Co. Ltd. (Beijing, China). 2-((*E*)-2-((*E*)-2-Chloro-3-(2-((*E*)-3,3-dimethyl-1-propylindolin-2-ylidene)ethylidene)cyclohex-1-en-1-yl)vinyl)-3,3-dimethyl-1-propyl-3H-indol-1-ium iodide (IR-780) was purchased from JiangSu Aikon Biomedical R&D Co., Ltd. (Nanjing, China). Resorcinol were purchased from Bide Pharmaceutical Technology Co., Ltd. (Shanghai, China). Deionized water was used to prepare the buffer solutions and as the analyte. For column chromatography, 300–400 mesh silica gel was used to purify the crude product.

<sup>1</sup>H NMR and <sup>13</sup>C NMR spectra were recorded on a Bruker AVANCE II-400 MHz spectrometer at 400 and 100 MHz in DMSO-*d*<sub>6</sub>, respectively. Tetramethylsilane (TMS) was used as an internal standard. All chemical shift data are reported in the standard  $\delta$  notation of parts per million (ppm). Splitting patterns were designed as follows: s (singlet), d (doublet), t (triplet) and m (multiplet). High-resolution mass spectra (HRMS) were measured on a Q-TOF Premier ESI mass spectrometer. Fourier transform-infrared spectra (FTIR) were measured on a Bruker INVENIO R, and pH values of the samples were measured using a PHS-3E pH meter. UV-visible spectra were measured on a Shimadzu UV-3600 spectrophotometer. Photoluminescence spectra were recorded on a Horiba Jobin Yvon Fluoromax-4 fluorescence spectrophotometer. Transient photoluminescence decay characteristics of the solution samples were recorded on a Single Photon Counting Controller FluoroHub-B (Horiba Jobin Yvon). Photographs were taken using a Huawei Mate20 smartphone.

### 1.2 Synthesis and Characterization.

Synthesis of (*E*)-2-(2-(6-hydroxy-2,3-dihydro-1H-xanthen-4-yl)vinyl)-3,3-dimethyl-1-propyl-3H-indol-1-ium iodide (**Cy**). Scheme S1 shows the synthetic route for the sensor **Cy**. Under a nitrogen atmosphere, resorcinol (110 mg, 1 mmol) and K<sub>2</sub>CO<sub>3</sub> (138 mg, 1 mmol) were added to a two-necked flask containing 5 mL anhydrous acetonitrile, and then the mixtures were stirred at room temperature for 20 min. After that, the acetonitrile solutions of IR-780 (267 mg, 0.2 mmol) were added to the reaction system, and the whole reaction was heated at 50 °C for 4 h. Then the solvent was removed by rotary evaporation, and the residual solid was chromatographed with a silica gel column using dichloromethane/methanol (50/1, v/v) as an eluent to finally obtain a blue-green powder (yield: 67%).

The reaction mechanism for the synthesis of **Cy** is unique. As shown in Scheme S2, IR-780 and resorcinol under the basic conditions will undergo the straightforward nucleophilic substitution of chlorine atom, retro-Knoevenagel reaction, cyclization reaction and dehydration reaction in sequence,<sup>1</sup> then finally obtain the target compound **Cy**. The molecular structure of the sensor **Cy** was characterized by <sup>1</sup>H NMR, <sup>13</sup>C NMR spectra, HRMS analyses and FTIR spectra (Figure S1-Figure S4). Due to the efficient hydrogen-deuterium exchange of the phenolic hydroxyl group of **Cy** in the deuterated reagent, the relevant hydrogen signal is indiscernible in the <sup>1</sup>H NMR spectrum. Hence, the FTIR spectrum was used for supplementary characterization, and the peak around 3100 cm<sup>-1</sup> indicates the existence of -OH. <sup>1</sup>H NMR (400 MHz, DMSO-*d*<sub>6</sub>) δ (ppm): 8.54 (d, *J* = 14.8 Hz, 1H), 7.75 (d, *J* = 6.0 Hz, 1H), 7.65 (d, *J* = 8.0 Hz, 1H), 7.55 (s, 1H), 7.52 (d, *J* = 8.8 Hz, 1H), 7.48 (d, *J* = 8.4 Hz, 1H), 7.41 (t, *J* = 7.2 Hz, 1H), 6.90 (s, 1H), 6.86 (dd, *J* = 8.4, 2.0 Hz, 1H), 6.49 (d, *J* = 14.8 Hz, 1H), 4.34 (t, *J* = 6.8 Hz, 2H), 2.72 (t, *J* = 5.6 Hz, 2H), 2.67 (t, *J* = 6.0 Hz, 2H), 1.85-1.80 (m, 4H), 1.75 (s, 6H), 0.99 (t, *J* = 7.2 Hz, 3H). <sup>13</sup>C NMR (100 MHz, DMSO-*d*<sub>6</sub>) δ (ppm): 176.7, 163.3, 161.4, 154.9, 144.3, 142.2, 135.2, 129.8, 129.3, 126.9, 125.8, 123.2, 115.8, 114.9, 114.4, 113.3, 103.6, 102.5, 50.5, 46.3, 28.7, 28.1, 24.1, 21.2, 20.5, 11.5. HRMS (ESI) *m/z* for C<sub>28</sub>H<sub>30</sub>INO<sub>2</sub> (M-I)<sup>+</sup> Calcd.: 412.2271, Found: 412.2275.

**Scheme S1.** Synthetic route of **Cy**.

**Scheme S2.** Reaction mechanism for the formation of **Cy**<sup>1</sup>.

### 1.3 Calculation of the $pK_a$ value

Prepare buffer solutions of the sensor **Cy** with various pH values from 4.01 to 10.02 and characterize the corresponding fluorescence spectra. The  $pK_a$  value of **Cy** was calculated by regression analysis of the fluorescence intensity as a function of pH, where the analysis should fit to the Henderson-Hasselbalch-type mass action equation:

$$\log \left[ \frac{(F_{\max} - F)}{(F - F_{\min})} \right] = pK_a - \text{pH}$$

Where  $F$  is the fluorescence emission intensity at 725 nm,  $F_{\max}$  and  $F_{\min}$  are the corresponding maximum and minimum limiting values of  $F$ , respectively.

### 1.4 Detection the relative content of $\text{H}_2\text{O}$ and $\text{D}_2\text{O}$

Typically, the stock solution of **Cy** was prepared by dissolving **Cy** in ultra-dry DMF

(2 mM). Then, 22.5  $\mu\text{L}$  Cy was added to  $\text{D}_2\text{O}$  (or  $\text{H}_2\text{O}$  or  $\text{D}_2\text{O}$ - $\text{H}_2\text{O}$  mixtures) and the final concentration of the sensor was 100  $\mu\text{M}$ . UV-vis absorption and fluorescence emission spectra were conducted on the as-prepared solution samples. During the measurements, the lids of the cuvettes are always closed to prevent  $\text{D}_2\text{O}$  from absorbing moisture so as to affect the analytical results. All the experiments were repeated in triplicate to obtain consistent values.

In all subsequent experiments, the concentration of the sensor solution was fixed at 100  $\mu\text{M}$  and the detection system contained 5 vol% DMF.

### **1.5 RGB colorimetric**

The stock solutions of the sensor Cy were added to different systems separately, which contained distinct  $\text{H}_2\text{O}$ - $\text{D}_2\text{O}$  relative content. The detection process is shown in Scheme 2. Pictures of samples were taken with a smartphone and opened with the smartphone analysis application (APP). The detection region was selected in the APP (*Palette Cam*). Generally, the middle part of the reaction solution was selected for sampling. The numerical values of RGB were computed by the APP software and the calibration curve was obtained through data analysis.

### **1.6 Method reliability**

Randomly prepare five samples with various  $\text{H}_2\text{O}$ - $\text{D}_2\text{O}$  content (unknown relative proportion). The prepared samples were subjected to analysis with FTIR spectra (classical instrumental method) and the proposed Cy sensor, including absorption, fluorescence and RGB three channels. The FTIR spectra of all samples were performed on a Bruker INVENIO R Fourier transform-infrared spectrophotometer with the attenuated total reflection (ATR) mode.

**Fig. S5** The fluorescence spectra of Cy in D<sub>2</sub>O and H<sub>2</sub>O, where the concentration of Cy is  $3.3 \times 10^{-5}$  mol/L (a),  $6.7 \times 10^{-5}$  mol/L (b),  $1.0 \times 10^{-4}$  mol/L (c),  $1.33 \times 10^{-4}$  mol/L (d),  $1.67 \times 10^{-4}$  mol/L (e) and  $2.0 \times 10^{-4}$  mol/L (f) respectively (inset: the photos of Cy in D<sub>2</sub>O and H<sub>2</sub>O, respectively). (g) Optimization diagram of the sensor concentration.

In the preliminary experiments, we found that the concentration of Cy could affect the output of the ratiometric signal, thus affecting the sensitivity of the sensor. On this basis, we optimized the concentration of Cy through comparing the difference of these ratiometric signals between D<sub>2</sub>O and H<sub>2</sub>O. As shown in **Fig. S5**, when the sensor concentration is  $1.33 \times 10^{-4}$  M, the ratio of ratiometric signal (R) reaches the maximum. Nevertheless, considering the effect of naked-eye visualization, we finally chosen the concentration of  $1 \times 10^{-4}$  M to realize the good sensitivity and distinct color difference at the same time.

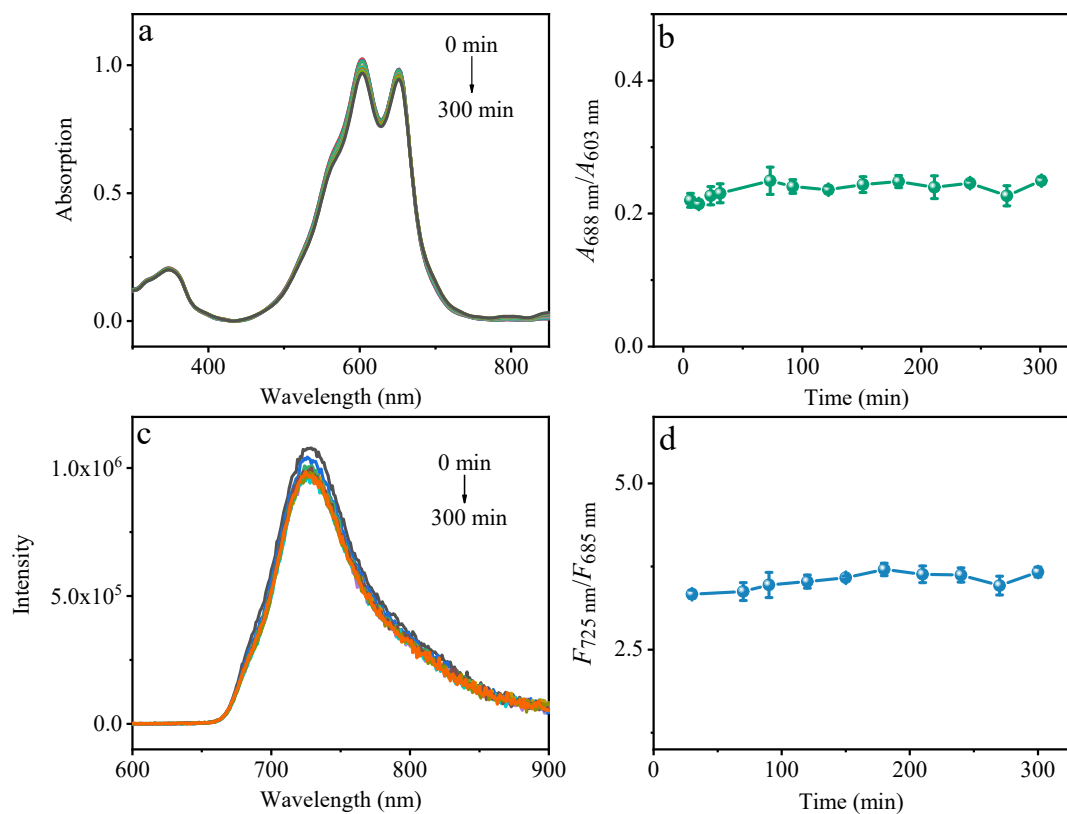

**Fig. S6** (a) UV-vis absorption spectra of Cy in H<sub>2</sub>O-D<sub>2</sub>O mixtures with different D<sub>2</sub>O fractions (0-50%, v/v). (b) Relationship between  $A_{688}/A_{603}$  of Cy with D<sub>2</sub>O content in total volume. (c) Fluorescence emission spectra of Cy in H<sub>2</sub>O-D<sub>2</sub>O mixtures with different D<sub>2</sub>O fractions (0-26%, v/v) ( $\lambda_{\text{ex}} = 580 \text{ nm}$ ). (d) Relationship between  $F_{725}/F_{685}$  values of Cy with D<sub>2</sub>O content in total volume (V<sub>total</sub> = V<sub>H<sub>2</sub>O</sub> + V<sub>D<sub>2</sub>O</sub>).

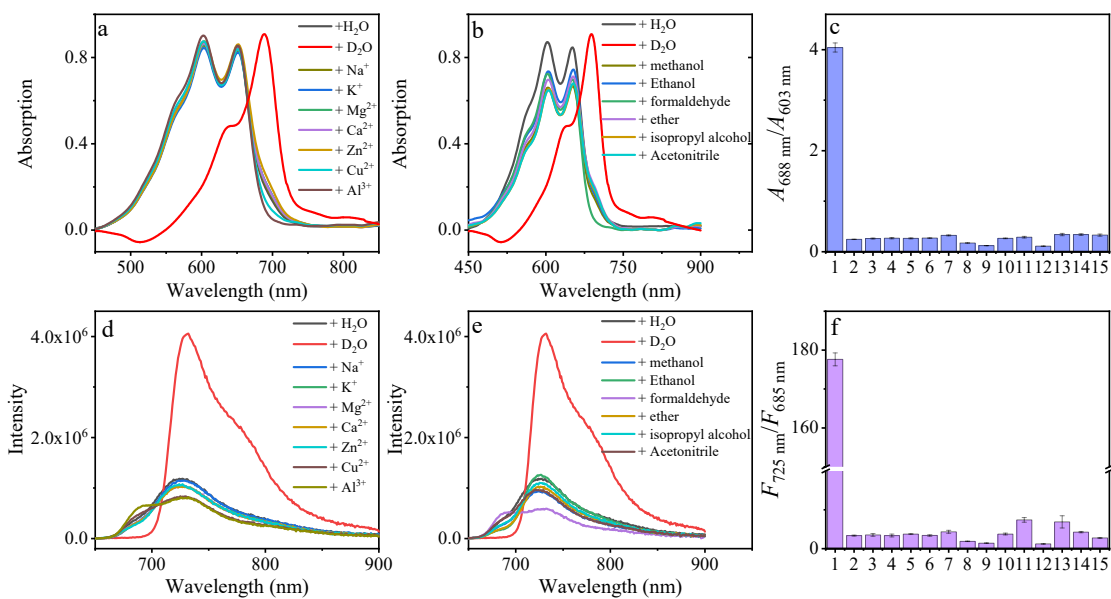

**Fig. S7** Fluorescence decay curves of **Cy** in D<sub>2</sub>O, H<sub>2</sub>O and 50 vol% of D<sub>2</sub>O monitored at (a) 685 nm and (b) 725 nm at 298K ( $\lambda_{ex} = 590$  nm, IRF: Instrument response function). (c) FTIR spectra of pure D<sub>2</sub>O and pure H<sub>2</sub>O.

**Table S2** The fitted photoluminescence lifetime data of **Cy** in D<sub>2</sub>O, H<sub>2</sub>O and 50 vol% of D<sub>2</sub>O at 298 K ( $\lambda_{ex} = 590$  nm).

**Table S6.** The advantages and disadvantages of representative D<sub>2</sub>O optical sensors.

| Sensor                   | Advantages                                                                                           | Disadvantages                                                                             |
|--------------------------|------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------|
| <b>NIM-2F</b>            | naked-eye visualization, absorption ratiometric response                                             | poor water-solubility, single channel response, insufficient detection sensitivity        |
| <b>AF</b>                | absorption/fluorescence dual-channel ratiometric response                                            | poor water-solubility and naked-eye visualization, insufficient detection sensitivity     |
| <b>CF-D<sub>2</sub>O</b> | water-solubility, two turn-on fluorescence signals response                                          | single channel response, poor naked-eye visualization, insufficient detection sensitivity |
| <b>ES</b>                | readily available sensor, absorption/fluorescence dual-channel response,                             | poor water-solubility and naked-eye visualization                                         |
| <b>TPA-DP-COOH</b>       | brilliant water-solubility and sensitivity of detection                                              | single channel response, poor naked-eye visualization                                     |
| <b>HIT</b>               | water-solubility, absorption/fluorescence dual-channel ratiometric response                          | insufficient naked-eye visualization and detection sensitivity                            |
| <b>Cy</b>                | water-solubility, absorption/fluorescence dual-channel ratiometric response, naked-eye visualization | insufficient detection sensitivity                                                        |
