Section 1. The data calibration method used for solubility/IDR measurements

Based on the linear absorption and constant proportion (1:1) of the two components in the present cocrystal, the Lambert-Beer's law is still applicable. We present the conversion process as the following equations:

$$A_{FCY} = \epsilon_{FCY} \times C_{FCY} \times L \quad (1)$$

$$A_{VAA} = \epsilon_{VAA} \times C_{VAA} \times L \quad (2)$$

In addition, because the proportion of the two components FCY and VAA in the present cocrystal, as well as the optical path length L , are constantly equal, then, the following relationship can be established:

$$C_{FCY} \times L = C_{VAA} \times L \quad (3)$$

Based on the above equations, it can obtain equation (4):

$$A_{FCY}/(A_{FCY} + A_{VAA}) = \epsilon_{FCY}/(\epsilon_{FCY} + \epsilon_{VAA}) = k \quad (4)$$

Where k is a constant, and also, because of the additive property of absorption, the $A_{FCY} + A_{VAA}$ is usually the read absorption in the experiments. Therefore, the actual absorption value of FCY is determined by substituting the measured values of FCY and VAA into the subsequently obtained equation (5). From the **Fig. S1**, it can be seen that the measured A_{FCY} and A_{VAA} are respectively 0.468 and 0.301, thus, the constant k value is calculated to 0.609. According to the result above, the actual absorption value of FCY in our experiments (denoted as A'_{FCY}) is obtained by multiplying the coefficient k with the read absorption value (denoted as A'_{read}) as follows:

$$A'_{FCY} = 0.609 \times A'_{read} \quad (5)$$

Table S1. pH values measured in different media after solubility tests.

Solution	pH (dissolution media)		
	1.20	4.00	6.80
pH (FCY solution)	1.92	4.11	6.91
pH (cocrystal solution)	1.27	4.09	6.85

Table S2. pH values measured in different media after IDR tests.

Solution	pH (dissolution media)		
	1.20	4.00	6.80
pH (FCY solution)	1.28	4.07	6.84
pH (PM solution)	1.22	4.01	6.79
pH (cocrystal solution)	1.25	4.04	6.81
