## Methods

### The Fewest-Switches Surface-Hopping Method

The trajectory-based fewest-switches surface-hopping dynamics simulation approaches by Tully et al.<sup>1</sup> has been extensively employed to simulate a variety of ultrafast excited-state relaxation processes in chemical/biological systems and materials.<sup>2–10</sup> In the following, a brief presentation is given.

Treating nuclear coordinates  $\mathbf{R}(t)$  as variables, the time-dependent electronic Schrödinger equation can be written as

$$i\hbar\dot{\Psi}(\mathbf{r}, \mathbf{R}(t), t) = \hat{H}_0(\mathbf{r}, \mathbf{R}(t))\Psi(\mathbf{r}, \mathbf{R}(t), t) \quad (\text{S1})$$

where  $\hat{H}_0(\mathbf{r}, \mathbf{R}(t))$  is the zero-order electronic Hamiltonian while  $\mathbf{r}$  represents the electronic coordinates. The time-dependent electronic wavefunction is then expressed in terms of a linear combination of adiabatic zero-order electronic spatial wavefunctions:

$$\Psi(\mathbf{r}, \mathbf{R}(t), t) = \sum_{i=1}^N C_i(t) \Psi_i(\mathbf{r}, \mathbf{R}(t)) \quad (\text{S2})$$

in which  $\Psi_i(\mathbf{r}, \mathbf{R}(t))$  is an eigenfunction of zero-order Hamiltonian  $\hat{H}_0(\mathbf{r}, \mathbf{R}(t))$  at nuclear coordinates  $\mathbf{R}(t)$ . Substituting Eq. S2 into Eq. S1, multiplying by  $\Psi_j^*(\mathbf{r}, \mathbf{R}(t))$  and integrating over the electronic coordinates, we obtain

$$\dot{C}_j(t) = -i\hbar^{-1} C_j(t) E_j(\mathbf{R}(t)) - \sum_i^N C_i(t) \tau_{ji}(t) \quad (\text{S3})$$

where  $\tau_{ji}(t) = \langle \Psi_j | \frac{\partial}{\partial t} \Psi_i \rangle$  is the time derivative nonadiabatic coupling between adiabatic states  $i$  and  $j$ .  $\tau_{ji}(t)$  can also be expressed as  $\mathbf{v}(t) \cdot \mathbf{d}_{ji}(\mathbf{R}(t))$  in which  $\mathbf{v}(t)$  and  $\mathbf{d}_{ji}(\mathbf{R}(t))$  are the nuclear velocities and the adiabatic derivative couplings, respectively. Thus, Eq. S3 can also be written as

$$\dot{C}_j(t) = -i\hbar^{-1} C_j(t) E_j^0(\mathbf{R}(t)) - \sum_i^N C_i(t) \mathbf{v}(t) \cdot \mathbf{d}_{ji}(\mathbf{R}(t)) \quad (\text{S4})$$

which is the central equation of the fewest-switches surface-hopping method and may describe radiationless transitions between electronic states with the same spin. The fewest-switches criterion finally yields the transition probability from state  $i$  to  $j$  as

$$p_{ij}(t) dt = 2 \frac{\text{Re}(C_i^* C_j \tau_{ij})}{C_i^* C_i} dt \quad (\text{S5})$$

This method has been implemented in our own GTSH package<sup>11</sup> and widely used to simulation photoinduced ultrafast processes of molecular, biological and materials systems.<sup>12–17</sup>

## The Time-Derivative Nonadiabatic Couplings

The time derivative nonadiabatic couplings  $\tau_{ji}(t)$  can be calculated from the adiabatic derivative couplings  $\mathbf{d}_{ji}(\mathbf{R}(t))$  and the nuclear velocities  $\mathbf{v}(t)$ , and there are also some analytical expressions for  $\mathbf{d}_{ji}(\mathbf{R}(t))$ .<sup>18–20</sup> In addition, there are two types of numerical algorithms available to directly compute  $\tau_{ji}(t)$  in the framework of TD-DFT.<sup>21,22</sup> Our present work uses the recently developed algorithm. A brief presentation is given below, in which the subscripts  $\{a, b, c\}$  denote the virtual orbitals,  $\{i, j, k\}$  the occupied orbitals, and  $\{p, q, r\}$  for any type of orbitals.

In TD-DFT the total electronic wave function of an electronically excited state  $\Psi_K$  is approximately written as a linear combination of singly-excited Slater determinants,

$$\Psi_K = \sum_i^{\text{occ}} \sum_a^{\text{unocc}} w_{ia}^K \psi_i^a \quad (\text{S6})$$

in which  $w_{ia}^K$  is the coefficient of the singly-excited Slater determinant  $\psi_i^a$ . The determinant  $\psi_i^a = \hat{a}_a^\dagger \hat{a}_i \psi_0$  is constructed through the electronic excitation (substitution) operation of the ground-state determinant  $\psi_0$ . Thereby, the time derivative nonadiabatic coupling  $\tau_{KJ} = \langle \Psi_K | \frac{\partial}{\partial t} \Psi_J \rangle$ , can be further written as

$$\tau_{KJ} = \sum_{ijab} \left( w_{ia}^{K*} \partial_t w_{jb}^J \left\langle \psi_i^a \middle| \psi_j^b \right\rangle + w_{ia}^{K*} w_{jb}^J \left\langle \psi_i^a \middle| \partial_t \psi_j^b \right\rangle \right) \quad (\text{S7})$$

The first term simplifies to  $\sum_{ia} w_{ia}^{K*} \partial_t w_{ia}^J$  due to the orthogonality condition for the molecular orbitals (MOs)  $\langle \phi_p | \phi_q \rangle = \delta_{pq}$ . The time differentiation on  $\psi_j^b$  gives

$$\partial_t \psi_j^b = \sum_{k \neq j} \psi_j^b \{k\}' + \psi_j^{b'} \quad (\text{S8})$$

where  $\psi_p^q \{r\}'$  denotes a determinant originated from  $\psi_p^q$  but with the MO  $\phi_r$  ( $r \neq p$ ) replaced by its time derivative  $\partial_t \phi_r$ , and  $\psi_p^{q'}$  denotes a determinant originated from  $\psi_p^q$  but with the MO  $\phi_p$  replaced

by the time derivative  $\partial_t \phi_q$ . Therefore, the 2nd term in formula S7 becomes

$$\left\langle \psi_i^a \left| \partial_t \psi_j^b \right. \right\rangle = \sum_{k \neq j} \left\langle \psi_i^a \left| \psi_{jk}^{bk'} \right. \right\rangle + \left\langle \psi_i^a \left| \psi_j^{b'} \right. \right\rangle \quad (\text{S9})$$

in which the last term above is reduced to  $\delta_{ij} \langle \phi_a | \partial_t \phi_b \rangle$ , while only one term with  $k = i$  and  $a = b$  from sum over  $k$  survives due to orthogonality conditions ( $\langle \phi_p | \partial_t \phi_p \rangle = 0$  for real orbitals;  $\langle \phi_p | \phi_q \rangle = \delta_{pq}$ ).

Then, we arrive at

$$\left\langle \psi_i^a \left| \partial_t \psi_j^b \right. \right\rangle = \delta_{ij} \langle \phi_a | \partial_t \phi_b \rangle - P_{ij} \delta_{ab} \langle \phi_j | \partial_t \phi_i \rangle \quad (\text{S10})$$

where  $P_{ij}$  is an additional phase factor that depends on the ordering convention for the orbitals used in the Slater determinants.

Finally, the computational expression for the time derivative nonadiabatic couplings is written as

$$\tau_{KJ} = \sum_{ia} w_{ia}^K \partial_t w_{ia}^J + \sum_{iab} w_{ia}^K w_{ib}^J \langle \phi_a | \partial_t \phi_b \rangle - \sum_{ija} P_{ij} w_{ia}^K w_{ja}^J \langle \phi_j | \partial_t \phi_i \rangle \quad (\text{S11})$$

in which the terms related to the time derivatives of MOs can be calculated using a finite-difference scheme

$$\langle \phi_p | \partial_t \phi_q \rangle = \frac{1}{\Delta t} \langle \phi_p(t) | \phi_q(t + \Delta t) \rangle \quad (\text{S12})$$

where  $\phi_p(t)$  and  $\phi_q(t + \Delta t)$  represent MOs at  $t$  and  $t + \Delta t$  times, respectively. The corresponding algorithm has been independently coded into a standalone module in our developed GTSH package.<sup>23–25</sup>

## Fragment-Based Exciton Analysis

There are several analysis methods capable of examining the excited-state characters, intra- and intermolecular electron and energy transfers of complex systems and in particular the donor–acceptor systems. One of the most popular methods is based on analyzing one-electron transition density matrices, which can be implemented in different atomic orbital representations, e.g. nonorthogonal atomic orbitals<sup>26</sup> or Löwdin orthogonalized atomic orbitals.<sup>27</sup> Recently we have implemented a similar analysis method using Löwdin orthogonalized atomic orbital representation.<sup>28</sup> Within such, the one-electron transition density

matrix  $\mathbf{T}_{LO}$  is expressed as

$$\mathbf{T}_{LO} = (\mathbf{S}_{AO})^{1/2} \mathbf{T}_{AO} (\mathbf{S}_{AO})^{1/2} = (\mathbf{S}_{AO})^{1/2} (\mathbf{C} \mathbf{T}_{MO} \mathbf{C}^T) (\mathbf{S}_{AO})^{1/2} \quad (S13)$$

where  $\mathbf{C}$  and  $\mathbf{S}_{AO}$  are the MO coefficients and AO overlap matrices, and  $\mathbf{T}_{AO}$  and  $\mathbf{T}_{MO}$  represent the one-electron transition density matrices in the AO and MO representations, respectively. Due to the orthogonal property of Löwdin atomic orbitals, the transition contribution from atom  $a$  to  $b$  becomes

$$D_{ab} = \sum_{i \in a, j \in b} (\mathbf{T}_{LO})_{ij}^2 \quad (S14)$$

where  $i$  and  $j$  are the indices of the atomic orbitals, and  $a$  and  $b$  are the indices of the atoms. Thus, transition contribution from a fragment  $D$  to another fragment  $A$  in a system is given by

$$\Omega_{DA} = \sum_{a \in D, b \in A} D_{ab} \quad (S15)$$

in which  $D = A$  and  $D \neq A$  represent the local excitation (LE) within fragment  $D$  and the charge transfer (CT) excitation from  $D$  to  $A$ , respectively. Accordingly, contributions of LE and CT to an excited state of interest can be quantitatively obtained. These  $\Omega_{DA}$  can also be regarded as weights of different fragment-based LE and CT excitons. Moreover, time-dependent electron and hole counts on a fragment can also be calculated.<sup>23–25</sup> The hole count on a fragment  $D$ , as a result of electron transfer from  $D$  to all fragments  $A$ , is computed as

$$h_D = \sum_{a \in D} D_{ab} = \sum_A \Omega_{DA} \quad (S16)$$

while, the electron count of a fragment  $A$  transferred from all fragments  $D$  is defined as

$$e_A = \sum_{b \in A} D_{ab} = \sum_D \Omega_{DA} \quad (S17)$$

## Electron-Hole Density

Electronic excitation always results in many pairs of hole and electron, which are represented as singly excited Slater determinants  $\psi_i^a$  in TD-DFT calculations (see above). These electron-hole pairs can be described by occupied and unoccupied MO indices. However, such kind of analysis could be complex if many pairs of MOs are involved. Instead, analyzing spatial distribution of electron and hole produced by all pairs of involved MOs is more useful. In such scheme, hole and electron densities are written as follows<sup>29,30</sup>

$$\rho^{hole}(\mathbf{r}) = \rho_{loc}^{hole}(\mathbf{r}) + \rho_{cross}^{hole}(\mathbf{r}) = \sum_{i \rightarrow a} (w_{ia})^2 \phi_i(\mathbf{r}) \phi_i(\mathbf{r}) + \sum_{i \rightarrow a} \sum_{j \neq i \rightarrow a} w_{ia} w_{ja} \phi_i(\mathbf{r}) \phi_j(\mathbf{r}) \quad (S18)$$

$$\rho^{electron}(\mathbf{r}) = \rho_{loc}^{electron}(\mathbf{r}) + \rho_{cross}^{electron}(\mathbf{r}) = \sum_{i \rightarrow a} (w_{ia})^2 \phi_a(\mathbf{r}) \phi_a(\mathbf{r}) + \sum_{i \rightarrow a} \sum_{i \rightarrow b \neq a} w_{ia} w_{ib} \phi_a(\mathbf{r}) \phi_b(\mathbf{r}) \quad (S19)$$

in which  $\sum_{i \rightarrow a} \equiv \sum_i^{occ} \sum_a^{vir}$  and  $\sum_{i \rightarrow a} \sum_{j \neq i \rightarrow a} \equiv \sum_i^{occ} \sum_{j \neq i}^{occ} \sum_a^{vir}$ ;  $w_{ia}$  is coefficient of excited Slater determinant  $\psi_i^a$  in an electronically excited electronic state;  $\phi_i(\mathbf{r})$  and  $\phi_j(\mathbf{r})$  are MOs that hole occupies;  $\phi_a(\mathbf{r})$  and  $\phi_b(\mathbf{r})$  are MOs that electron occupies. In these equations, the first and second terms stand for contributions of local and cross terms. It is clear that these two electron and hole densities satisfy  $\int \rho^{hole}(\mathbf{r}) d\mathbf{r} = 1$  and  $\int \rho^{electron}(\mathbf{r}) d\mathbf{r} = 1$  due to orthonormality properties of MOs and total sum of squares of all configuration coefficients is 1.0, which means that only one electron is excited leaving one hole. On the basis of electron and hole densities, useful parameters to characterize electron-hole separation can be defined, such as distance of centroids of electron and hole.

Based on density distributions of hole and electron, centroids of hole and electron can be calculated to approximately represent positions of hole and electron. In such case, centroid coordinates  $X$ ,  $Y$ , and  $Z$  of electron can be calculated as

$$X_{electron} = \int x\rho^{electron}(\mathbf{r})d\mathbf{r} \quad (S20)$$

$$Y_{electron} = \int y\rho^{electron}(\mathbf{r})d\mathbf{r} \quad (S21)$$

$$Z_{electron} = \int z\rho^{electron}(\mathbf{r})d\mathbf{r} \quad (S22)$$

where  $x$ ,  $y$ , and  $z$  are Cartesian coordinate components of electron. Similarly, one can define those for hole.

## Semi-Classical Spectra Simulation

Absorption spectra are simulated with a semi-classical method proposed by Barbatti et al.<sup>31,32</sup> On the basis of ground-state ensembles composed of  $N$  structures  $\mathbf{R}_k$ , we can calculate photoabsorption cross section with time-dependent perturbation theory at the first-order level

$$\sigma(E) = \frac{\pi e^2}{2mc\varepsilon_0} \sum_{l \neq i} \left[ \frac{1}{N} \sum_k f_{il}(\mathbf{R}_k) g(E - \Delta E_{il}(\mathbf{R}_k), \delta) \right] \quad (S23)$$

where  $\varepsilon_0$  is vacuum dielectric constant;  $c$  is speed of light;  $e$  and  $m$  are electron charge and mass;  $f_{il}(\mathbf{R}_k)$  and  $\Delta E_{il}(\mathbf{R}_k)$  are oscillator strength and transition energy from initial  $i$  to final  $l$  state at structure  $\mathbf{R}_k$ ;  $g(E - \Delta E_{il}(\mathbf{R}_k), \delta)$  is a normalized line shape function that is peaked at transition energy  $\Delta E_{il}(\mathbf{R}_k)$  and broadened by a phenomenological constant  $\delta$ . In practical applications, there are two kinds of shape functions used to model line shapes. The first one is Gaussian shape function

$$g_{Gauss}(E - \Delta E_{il}, \delta) = \left( \frac{2}{\pi} \right)^{1/2} \frac{\hbar}{\delta} \exp \left( \frac{-2(E - \Delta E_{il})^2}{\delta^2} \right) \quad (S24)$$

the second one is Lorentzian shape function

$$g_{Lorenz}(E - \Delta E_{il}, \delta) = \frac{\hbar\delta}{2\pi} \left[ (E - \Delta E_{il})^2 + \left(\frac{\delta}{2}\right)^2 \right]^{-1} \quad (S25)$$

in which  $\hbar$  is reduced Planck constant. Our group has recently implemented this method for absorption spectra simulations.<sup>23–25,28</sup> In the present work, Gaussian shape function is used for simulating absorption spectra from ground to excited state ( $i = 0$ ).
