2. Experimental and Theoretical Details for Choosing the Number of Methanol

Alcohol, like water, is an amphiprotic solvent, but with only one hydrogen bond donating site. In contrast to water, alcohol's hydrogen bond typically takes the form of a chain. To accurately describe the relationship between the pseudo-first-order decay rate constant and the methanol concentration (see Fig. S2), the following equations are used:

$$k = k_0 + k_M[\text{MeOH}]^n \quad (1)$$

$$\log(k - k_0) = \log(k_M) + n \cdot \log[\text{MeOH}] \quad (2)$$

where k and k_0 are the observation rate constants in the presence and absence of methanol, respectively.

The rate constant for the reaction of ${}^3\text{NO}_2\text{-Bp-OH}$ with methanol is given by k_M . Eq.(2) is obtained by performing the logarithm transformation on two sides of Eq.(1). The slope value of $n=3.0\pm 0.18$ is obtained by fitting the plot of the logarithm of $k-k_0$ vs. the logarithm of methanol concentration with a linear function. The result of $n=3$ suggests that the methanol trimer is required to quench ${}^3\text{NO}_2\text{-Bp-OH}$.

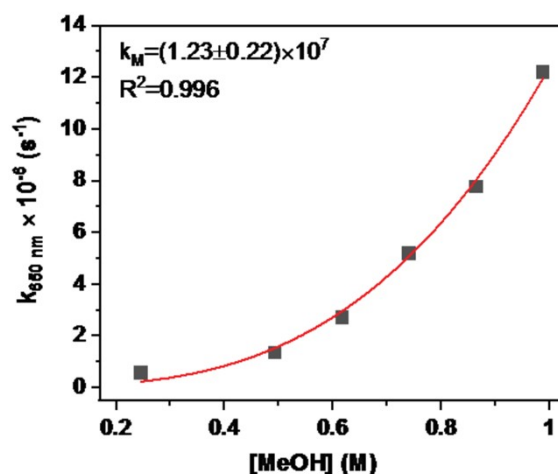

Figure S2. The pseudo-first-order decay time constants (solid squares) obtained by fitting the 650 nm kinetics with a single exponential function versus methanol concentrations, and the fitting curve (red curve) obtained with the equation $k = k_0 + k_M[\text{MeOH}]^3$.

Moreover, the potential energy surfaces of methanol oligomer assisted deprotonation in ${}^3\text{NO}_2\text{-Bp-OH}$ are simulated using theoretical calculations, as shown in Fig. S3. The deprotonation barrier can be significantly reduced by increasing the number of methanol molecules around the hydroxyl group of ${}^3\text{NO}_2\text{-Bp-OH}$, and it is reduced to 3.7 kcal/mol in the methanol trimer structure. As the O-H distance in ${}^3\text{NO}_2\text{-Bp-OH}$ increases, the energy surfaces of a single and two methanol molecules continue to grow, while the energy surface of three, four, and five methanol molecules exhibits minima. The energy barrier is slightly lower for four and five methanol molecules than that for three methanol molecules. This comes as no surprise given that the larger the cluster size, the more stable the structure. The greater the number of methanol molecules, the easier it is to deprotonate and stabilize the proton, but three-methanol is the critical size.

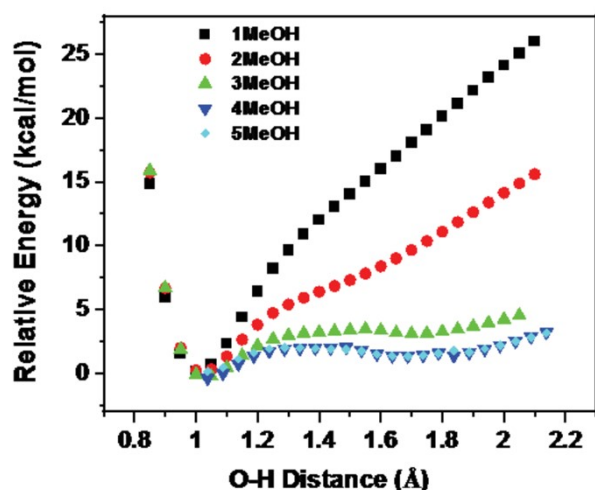

Figure S3. Potential energy curves of the T_1 state $\text{NO}_2\text{-Bp-OH}\cdots (\text{MeOH})_n$ ($n=1-5$) hydrogen-bonded complexes in acetonitrile, obtained from the relaxed scans along the O-H (in $\text{NO}_2\text{-Bp-OH}$) stretching

coordinate (step length=0.05 Å). The relative energy values are calculated in comparison to the corresponding hydrogen-bonded complexes in the S₀ state.
