**Part 1.** B1 diagnostics.

**Part 2.** Reaction rate calculation.

**Part 3.** The relative energies between the different isomers of chain structures.

**Part 4.** Bond properties of C-C bonds on the main chain of different chain structures.

**Part 5.** Spin population of different structures.

**Part 6.** The degradation reactions related to the tail end of structures.

**Part 7.** The EDA between the first monomer and the remaining fragments in different structures.

**Part 8.** The frontier molecular orbitals of different structures.

**Part 1. B<sub>1</sub> diagnostics.**

B<sub>1</sub> diagnosis is an effective method to measure the multireference characters of systems<sup>1-3</sup>, which can be defined as:

$$B_1 = (BE_{BLYP} - BE_{B1LYP//BLYP})/n$$

where,  $BE_{BLYP}$  and  $BE_{B1LYP//BLYP}$  are the bond energies computed with BLYP and B1LYP//BLYP,  $n$  is the number of bonds being broken. If the value (divided by 1 kcal/mol to produce a unitless diagnostic) of B<sub>1</sub> diagnostic exceeds 10.0, the multireference methods should be considered.

Table S1. The B<sub>1</sub> values of different structures.

|                       | PAMS | R1   | R2-1 | R2-2 | R3-1 | R3-2 | R4-1 | R4-2 | R4-3 | R4-4 |
|-----------------------|------|------|------|------|------|------|------|------|------|------|
| B <sub>1</sub> Values | 4.15 | 3.00 | 4.38 | 3.46 | 4.15 | 3.23 | 4.38 | 4.38 | 3.92 | 3.69 |

**Part 2. Reaction rate calculation.**

Reaction rate constants were also calculated in terms of the transition state theory (TST) with Eckart Tunneling corrections<sup>4,5</sup>. The equation presented for the conventional TST is:

$$k^{TST}(T) = \sigma \frac{k_b T}{h} \left( \frac{RT}{P^0} \right)^{\Delta n} e^{-\frac{\Delta G^{\ddagger,0}(T)}{k_b T}}$$

where  $\sigma$  is the reaction path degeneracy,  $k_b$  is the Boltzmann's constant,  $T$  is the temperature,  $h$  is the Planck's constant,  $R$  is the ideal gas constant,  $P^0$  is the pressure,  $\Delta G^{\ddagger,0}(T)$  represents the standard Gibbs free energy ( $\Delta n = 1$  for gas-phase bimolecular). If the tunneling corrections are considered, then  $k^{TST/T}(T) = \chi(T) \times k^{TST}(T)$ . Where  $\chi(T)$  is transmission coefficient. As for Eckart correction, then

$$\chi(T) = \frac{e^{-\frac{\Delta H_f^{\pm,0K}}{k_b T}}}{k_b T} \int_0^{\infty} p(E) e^{-\frac{E}{k_b T}} dE$$

Where 
$$p(E) = 1 - \left[ \frac{\cosh\left[\frac{2\pi(\alpha - \beta)}{C}\right] + \cosh\left[\frac{2\pi\delta}{C}\right]}{\cosh\left[\frac{2\pi(\alpha + \beta)}{C}\right] + \cosh\left[\frac{2\pi\delta}{C}\right]} \right]$$

$$\alpha = \frac{1}{2\sqrt{C}}\sqrt{E} \quad \beta = \frac{1}{2\sqrt{C}}\sqrt{E - A} \quad \delta = \frac{1}{2\sqrt{C}}\sqrt{E - B}$$

$$A = \Delta H_f^{\pm,0K} - \Delta H_r^{\pm,0K}$$

$$B = (\sqrt{\Delta H_f^{\pm,0K}} - \sqrt{\Delta H_r^{\pm,0K}})^2$$

$$C = (h \text{Im}(v^{\ddagger}))^2 \left[ \frac{B^3}{A^2 - B^2} \right]^2$$

$\Delta H_f^{\pm,0K}, \Delta H_r^{\pm,0K}$  represent the zero-point corrected energy barriers in the reverse and forward direction,  $\text{Im}(v^{\ddagger})$  is the imaginary frequency.

**Part 3.** The relative energies between the different isomers of chain structures.

Table S2. The relative energies between the different isomers of the structures with cyclopentadiene, naphthalene or azulene as the side chain.

|                 | R2-1 | R2-2 | R3-1 | R3-2 | R4-1 | R4-2 | R4-3 | R4-4 |
|-----------------|------|------|------|------|------|------|------|------|
| $\Delta E$ (eV) | 0    | 1.73 | 0    | 1.18 | 0    | 0.66 | 1.02 | 2.08 |

**Part 4.** Bond properties of C-C bonds on the main chain of different chain structures.

**Table S3.** Bond lengths and bond orders of C-C bonds (a-g) on the main chain of different chain structures. The specific location can be seen in schematic diagram.

|      | Bond Length (Å)/Bond Order |          |          |          |          |          |          |

**Part 8.** The frontier molecular orbitals of different structures.

As can be seen from Fig. S4 below, the frontier MOs of different structures are all not only distributed on unsaturated carbon atoms, but delocalize to adjacent cyclic functional groups. But the degree of delocalization of these orbitals of different structures is different. Taking the HOMO- $\alpha$  as an example, it is mainly distributed at the unsaturated head-end and the nearby cyclic functional groups. But the compositions of this orbital for different substituted structures are not the same.

Table S6 shows the contributions of unsaturated carbon atom and cyclic functional groups to HOMO- $\alpha$ . Among all the substituted structures, the unsaturated carbon atom of R1 contributes the most to the HOMO- $\alpha$ , while that of R4-2 contributes the least, indicating that the HOMO- $\alpha$  of R1 is mainly localized on the unsaturated carbon atom, while this orbital of R4-2 is more delocalized. It is worth noting that the C-C bond attached to the unsaturated carbon atoms is broken in the head-end depolymerization reaction. Thus, the orbital delocalization explains the lower energy barrier required for head-end depolymerization of R1, while the higher energy barrier required for that of R4-2.

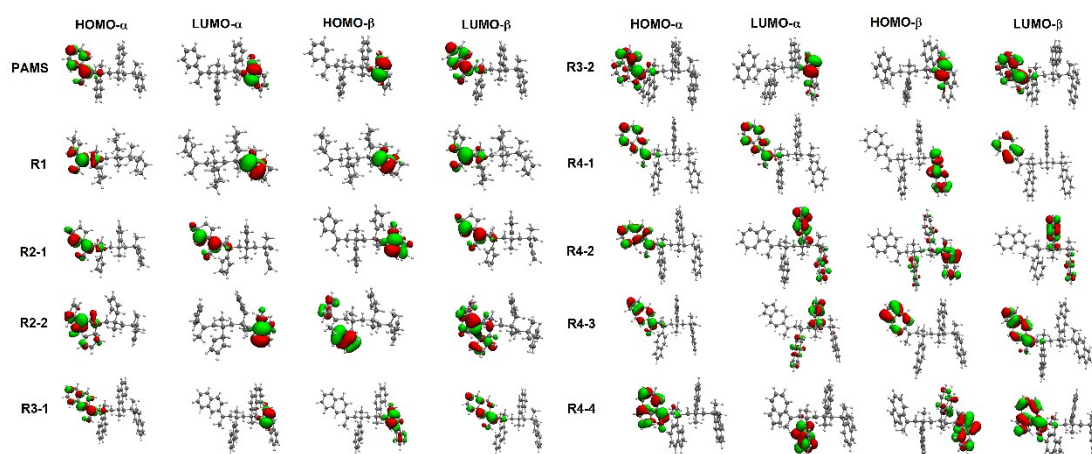

Fig. S4. The frontier molecular orbitals (MOs) of different substituted structures. Isovalue= 0.035.

Table S6. The contributions of unsaturated carbon atom and cyclic functional groups to HOMO- $\alpha$ .

|                                | PAMS  | R1    | R2-1  | R2-2  | R3-1  | R3-2  | R4-1  | R4-2  | R4-3  | R4-4  |
