Experimental Section

Synthesis of catalyst precursors:

Typically, 0.38 g $\text{Cu}(\text{NO}_3)_2 \cdot 3\text{H}_2\text{O}$, 0.14 g $\text{Fe}(\text{NO}_3)_3 \cdot 9\text{H}_2\text{O}$ and 0.5 g LDH ($\text{Mg}_6\text{Al}_2(\text{CO}_3)(\text{OH})_{16} \cdot 4\text{H}_2\text{O}$) were dissolved in 20 mL deionized water. Then the ethanol (10 mL) was added into the mixture and ultrasound-treated for 5 min to benefit the uniform dispersion of the LDH. All the water was evaporated through a simple evaporation process under magnetic stirring of the heating magnetic stirrer. Then the sample was transferred into a vacuum drying oven and dried at 70°C for 12 h to obtain the final powder. Following the same procedure, the powder samples consist of different components supported by different supports (Al_2O_3 , MgO etc.) were synthesized follow the same procedure.

For comparison, the T-CuO_x&FeO_y/MAO catalyst was obtained by calcining the powder in 10% H₂-Ar at 1015°C for 2 h.

Characterizations of catalysts:

The crystal structure was characterized by X-ray diffractometer (D/max-2500, Rigaku, Japan). The light adsorption properties of the catalysts were measured by Ultraviolet-visible (UV-Vis) spectroscopy (UV-2700, Shimadzu, Japan). The microstructure of the catalyst was performed on Scanning electron microscopy (SEM, Quanta FEG 250) and Transmission electron microscopy (TEM, JEM-F200). The spatial distribution of element was confirmed by energy-dispersive X-ray spectroscopy (EDS). The chemical valence state of the element was measured by Xray photoelectron spectroscopy (XPS, Escalab 250Xi, Thermo Fisher Scientific, England). Fourier transform infrared spectroscopy (FT-IR) was recorded by Nicolet 6700 Fourier transform instrument. The Brunauer-Emmett-Teller (BET) surface area and pore structure of the catalyst were analyzed by BET surface area measurement (Autosorb IQ2, Quantachrome, U.S.A.). The temperature of the catalyst surface was measured by a thermocouple (DT-311N).

Activity evaluation:

The reverse water gas shift (RWGS) reaction was carried out in a flow-type photothermal reactor. The process was as follows: 30 mg of the catalyst powder was spread onto a round shape air-permeable quartz fiber filter that was fixed on the sample stage of the reactor. The reaction gases of H₂ and CO₂ (the molar ratio of H₂: CO₂ = 1: 1) were injected into the reactor and the total flowrate was 400.0 mL min⁻¹. A 300 W Xe lamp (CEL-HXF300, CEAULIGHT) equipped with a quartz convergent lens group (FF50Q, MEIWO) was used as the light source, the power of the incident irradiation was 41.3 W (1.42 W/cm²). The focused irradiation areas of Xe lamp with and without quartz convergent lens group were 29.09 and 0.95 cm², respectively. Thus, the irradiation intensity was 439.4 kW m⁻² (439.4 suns) over catalyst surface. The gas products were detected by gas chromatography (GC-2014C, Shimadzu Co., Japan) equipped with a Poropak Q chromatographic column, a flame ionization detector (FID) and a methanizer. The flow rates of the gas products were measured by a soap flowmeter. The temperature of the catalyst surface was measured using a digital thermocouple (CUSTOM CT-1200D).

The calculations of gas conversion and generation rates:

$$CO_2(\%) = \frac{Inlet(CO_2) - outlet(CO_2)}{Inlet(CO_2)} \times 100\% \quad (1)$$

$$r(CO) = \frac{c(CO) * F}{m} \quad (2)$$

$$Sel(CO) = \frac{m * r(CO)}{Inlet(CO_2) - outlet(CO_2)} \times 100\% \quad (3)$$

Where $CO_2(\%)$ represents the conversion of CO₂, $Inlet(CO_2)$ and $Outlet(CO_2)$ represent the flow rate of CO₂ at the inlet and outlet; $r(CO)$ represents the generation rates of CO, F represents the total flow rate of the products, $c(CO)$ represents the mole percent of CO in it, m represents the mass of the catalyst; $Sel(CO)$ represent the selectivity of CO, respectively.
