## 1. General procedures of laboratory

All experiments involving moisture-sensitive compounds were performed under an inert atmosphere of $\mathrm{N}_{2}$ using standard Schlenk techniques or a glovebox. Deuterated solvents were degassed and dried over activated molecular sieves prior to use. 1-Chloroanthraquinone and hydrazine hydrate were purchased from Sigma-Aldrich and used as received. Acetone, 2quinoline carboxaldehyde, salicylaldehyde and benzaldehyde were purchased from Acros and used for the synthesis of $\mathbf{1}$ without further purification. THF, hexane and diethyl ether used for air sensitive processes were dried and degassed in a Solvent Purification System. LiHMDS was purchased from ABCR and used as received. $L$ - and rac-lactide were purchased from Acros and recrystallized with toluene three times before used. MALDI-TOF mass spectra were acquired using a mass spectrometer Bruker Autoflex Speed system (Bruker, Germany). Diffusion NMR measurements, average molecular weights, and hydrodynamic radii calculations were performed as previously reported. ${ }^{1}$

NMR spectra were measured in a Bruker Avance III 500 spectrometer. IR (ATR and DRIFT) spectra were recorded in a FT-IR Bruker Alpha spectrometer. Elemental analyses (EA) were performed on an Elementar vario EL cube in the CHN mode. Mass spectra were acquired using a mass spectrometer Orbitrap Thermo Fisher Scientific (ExactiveTM, Thermo Fisher Scientific, Bremen, Germany) using an electrospray interface (ESI) (HESI-II, Thermo Fisher Scientific, San Jose, CA, USA). The ESI parameters for the spectrometric detection, were as follows: spray voltage, 4 kV ; sheath gas ( $\mathrm{N}_{2},>95 \%$ ), 35 (adimensional); auxiliary gas ( $\mathrm{N}_{2},>95 \%$ ), 10 (adimensional); skimmer voltage, 18 V ; capillary voltage, 35 V ; tube lens voltage, 95 V ; heater temperature, $305{ }^{\circ} \mathrm{C}$; capillary temperature, $300^{\circ} \mathrm{C}$. The mass spectra were acquired employing two alternating acquisition functions: (1) full MS, ESI + , without fragmentation (the higher collisional dissociation (HCD) collision cell was switched off), mass resolving power $=25000$ full width at half maximum (FWHM); scan time $=0.25 \mathrm{~s}$, (2) full MS, ESI- using the aforementioned settings, (3) all-ions fragmentation (AIF), ESI + , with fragmentation (HCD on, collision energy 30 eV ), mass resolving power $=10000 \mathrm{FWHM}$; scan time $=0.10 \mathrm{~s}$, and (4) AIF, ESI- using the settings explained for (3).

## 2. General procedures

General procedure for the synthesis of ligands. Ligands 1 were synthesized from 1hydrazinoanthraquinone, which was prepared following a method previously described in the literature. ${ }^{[28]} 1$-Hydrazinoanthraquinone ( 7.2 mmol ) was suspended in methanol $(250 \mathrm{~mL})$, and the corresponding aldehyde or ketone ( $8.7 \mathrm{mmol}, 1.2$ equiv.) was added. The mixture was stirred and refluxed for 3.5 h , after which a red precipitate was observed. The suspension was cooled to room temperature, and the pure product was obtained as a deep red powder by filtration under reduced pressure.

General procedure for the synthesis of Li-complexes 2. Li-complexes were synthesized following a described procedure.[27] LiHMDS ( $42 \mathrm{mg}, 0.238 \mathrm{mmol}$ ) was dissolved in THF ( 10 mL ) and added to a suspension of 1 ( $0.238 \mathrm{mmol}, 1.0$ equiv.) in THF ( 10 mL ). The resulting deep green solution was stirred for 2 h at room temperature, and then all the volatiles were removed under vacuum. The remaining solid was washed with hexane $(15 \mathrm{~mL})$ and filtered out to yield the pure product as a dark green powder.

General procedure for the catalytic ROP of L- and rac-LA. It was conducted in a glovebox by dissolving LiHMDS ( $2 \mathrm{mg}, 0.012 \mathrm{mmol}$ ) and the corresponding ligand $1(0.012 \mathrm{mmol})$ in 1.2 mL of DCM or THF in a 5 mL capped vial equipped with a magnetic stirring bar. Once the catalyst was completely dissolved, the addition of L- or rac-Lactide ( $87 \mathrm{mg}, 0.6 \mathrm{mmol}$ ) was carried out and the reaction was left to stir overnight at room temperature until complete conversion of the starting material was reached. The reaction was then quenched with HCl 1 M (few drops), precipitated with cold methanol, and washed and centrifuged ( $11000 \mathrm{rpm}, 18^{\circ} \mathrm{C}, 10 \mathrm{~min}$.) with cold $\mathrm{MeOH}(3 \times 10 \mathrm{~mL})$. The pure polymer was finally dried under vacuum.

General procedure for the catalytic ROP of $\varepsilon$-Caprolactone. It was conducted in a glovebox by dissolving LiHMDS ( $2 \mathrm{mg}, 0.012 \mathrm{mmol}$ ) and the corresponding ligand $1(0.012 \mathrm{mmol})$ in 1.2 mL of DCM or THF in a 5 mL capped vial equipped with a magnetic stirring bar. Once the catalyst was completely dissolved, the addition of $\varepsilon$-Caprolactone ( $64 \mu \mathrm{~L}, 0.6 \mathrm{mmol}$ ) was carried out and the reaction was left to stir overnight at room temperature until complete conversion of the starting material was reached. The reaction was then quenched with HCl 1 M (few drops), precipitated with cold methanol, and washed and centrifuged ( $11000 \mathrm{rpm}, 18^{\circ} \mathrm{C}, 10 \mathrm{~min}$.) with cold $\mathrm{MeOH}(3$ $\mathrm{x} 10 \mathrm{~mL})$. The pure polymer was finally dried under vacuum.

General procedure for NMR monitored reactions. In a glovebox, the corresponding Li complex $2(0.006 \mathrm{mmol})$ was dissolved in 0.6 mL of $\mathrm{DCM}-\mathrm{d}_{2}$ in a 1.5 mL capped vial equipped with a magnetic stirring bar. Then, addition of $L$ - or rac-lactide ( $21.6 \mathrm{mg}, 0.3 \mathrm{mmol}$ ) was carried out and the solution was then immediately transferred into an oven-dried 5 mm NMR J-Young tube. The sample tube was shaken to ensure the homogeneity of the mixture and then placed inside the NMR spectrometer to perform the corresponding measurements.

Quantitative NMR acquisition parameters. ${ }^{1} \mathrm{H}$ NMR determination of product conversion was carried out by comparing signals arising from both CH of substrate and product. The standard acquisition parameters were one-dimensional pulse sequence which includes a $30^{\circ}$ flip angle (Bruker zg30), recycle time ( $\mathrm{D} 1=30 \mathrm{~s}$ ), time domain ( $\mathrm{TD}=64 \mathrm{k}$ ), number of scans ( $\mathrm{NS}=1$ ), acquisition time $(\mathrm{AQ}=2.97 \mathrm{~s})$, transmitter (frequency) offset $(\mathrm{O} 1 \mathrm{P}=8.0 \mathrm{ppm})$, and spectral width (SW = 22.0 ppm ).

Diffusion NMR Spectroscopy of complexes 2. NMR samples were prepared with different concentrations of complexes ( $10,20,40 \mathrm{mM}$ ) in 0.5 mL of THF- $\mathrm{d}_{8}$ in an oven-dried 5 mm NMR tube. The $\Delta$ and $\delta$ values varied from 75 to 100 ms for ${ }^{1} \mathrm{H}$ and 75 ms for ${ }^{7} \mathrm{Li}$; and from 2.5 to 3.5 ms , respectively. The gradient strength was incremented in steps of $4 \%$ starting from $8 \%$ to $96 \%$, so that 23 points were used for regression analysis. The recovery delay was always set to 5 s . The number of scans per increment were 32 and typical experimental times were around 3 h . All experiments were run without spinning. To check reproducibility and lack of convection, two different measurements with different $\Delta$ were always carried out. The contribution of convection to the calculated D values seems to be negligible since it remains always constant under the two different diffusion times assayed. Determination of the D-values was performed by applying different algorithms. dART solutions were obtained by the use of an algebraic reconstruction technique. ${ }^{1}$ TRAIn solutions were obtained by the use of the algorithm provided by Xu et al, ${ }^{2}$ with an alpha parameter set to 1.05 . LMS fittings were performed with the help of the DiffAtOnce package. ${ }^{3}$

Diffusion NMR Spectroscopy of cPLA polymers. NMR samples were prepared by just adding 1.5 mg of each polymer together with 0.5 mL of $\mathrm{CDCl}_{3}$ in an oven-dried 5 mm NMR tube. The $\Delta$ and $\delta$ values varied from 75 to 100 ms , and from 2.5 to 3.5 ms , respectively. The gradient strength was incremented in steps of $4 \%$ starting from $8 \%$ to $96 \%$, so that 23 points were used for regression analysis. The recovery delay was always set to 5 s . The number of scans per increment were 32 and typical experimental times were around 3 h . All experiments were run without spinning. To check reproducibility and lack of convection, two different measurements with different $\Delta$ were always carried out. The contribution of convection to the calculated D values
seems to be negligible since it remains always constant under the two different diffusion times assayed. Determination of the D -values was performed as mentioned before.

MALDI-TOF MS. Solutions of the polymer sample ( $10 \mathrm{mg} / \mathrm{mL}$ ) and matrix DCTB ( $20 \mathrm{mg} / \mathrm{mL}$ ) were prepared in dichloromethane (DCM):methanol (1:1). TFANa ( $10 \mathrm{mg} / \mathrm{mL}$ ) in DCM:MeOH (1:1) was employed as additive. $1 \mu \mathrm{~L}$ of the 10:1:0.5 ( $\mathrm{v} / \mathrm{v} / \mathrm{v}$ ) mixture Matrix:Polymer:TFANa was spotted via micropipet for MALDI analysis.

FT-IR spectra were recorded in the range $400-4000 \mathrm{~cm}^{-1}$ with a Bruker Vertex 70 equipped with a cell for liquid samples.

Computational details. Density functional theory (DFT) simulations were carried out with the M06-2X density functional ${ }^{4}$ and an ultrafine grid as implemented in Gaussian $16 .{ }^{5}$ Geometry optimizations were performed in THF using the continuum solvent approach SMD. ${ }^{6}$ The 6$31 \mathrm{G}(\mathrm{d}, \mathrm{p})$ basis set was used for all atoms, ${ }^{7}$ and diffuse functions were added for O atoms. ${ }^{8}$ Vibrational frequencies were computed to confirm the nature of minima. Those frequencies below $50 \mathrm{~cm}-1$ were replaced by $50 \mathrm{~cm}^{-1}$ when computing vibrational partition functions ${ }^{9}$ using the software GoodVibes. ${ }^{10}$ Gibbs energies are computed at 298 K and $1 \mathrm{M}(12.33 \mathrm{M}$ for a THF molecule in THF solution). Several conformations are searched for each species but only the most stables ones are reported. For the prediction of ${ }^{15} \mathrm{~N}$ and ${ }^{7} \mathrm{Li}$ NMR chemical shifts, isotropic shielding constants were computed with the gauge-independent atomic orbital method (GIAO). ${ }^{11}$ Single-point calculations were performed with the mPW1PW91 density functional ${ }^{12}$ and the 6 $311 \mathrm{G}(2 \mathrm{~d}, \mathrm{p})$ basis set ${ }^{8,13}$ in THF. This level of theory has been successful for predicting chemical shifts. ${ }^{14}$ For ${ }^{15} \mathrm{~N}$, only chemical shift differences between the free ligand and the complexed ligand are reported. For ${ }^{7} \mathrm{Li}$, the cation $\left[\mathrm{Li}(\mathrm{THF})_{4}\right]^{+}$is taken as reference, where the computed isotropic shielding constant is matched to the experimental chemical shift of $-0.45 \mathrm{ppm} .{ }^{15}$ All inputs and outputs can be consulted in the open-access ioChem-BD repository ${ }^{16}$ via the following database. ${ }^{17}$

## 4. Crystallographic Data of ligands 1 b and 1d

Single-crystal diffraction data were collected at 100(2) K on a Bruker D8 Venture with a Photon detector equipped with graphite monochromated $\operatorname{MoK} \alpha$ radiation $(\lambda=0.71073 \AA)$. The data reduction was performed with the APEX2 software and corrected for absorption using SADABS. Crystal structures were solved by direct methods using the SIR97 program and refined by fullmatrix least-squares on F2 including all reflections using anisotropic displacement parameters by means of the WINGX crystallographic package. Generally, anisotropic temperature factors were assigned to all atoms except for hydrogen atoms, which are riding their parent atoms with an isotropic temperature factor arbitrarily chosen as 1.2 times that of the respective parent. Several crystals of 1 b and 1 d were measured and the structure was solved from the best data we were able to collect, due to the fact that the crystals diffracted very little. Solvent mask routine (implemented in OLEX2 software) was used to eliminate one disordered crystallization dichloromethane molecule. Final R(F), wR(F2) and goodness of fit agreement factors, details on the data collection and analysis can be found in Table S1. Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication nos. CCDC 2193241-2193242 for compounds. Copies of the data can be obtained free of charge on application to the Director, CCDC, 12 Union Road, Cambridge, CB2 1EZ, U.K. (Fax:+44-1223-335033; e-mail: deposit@ccdc.cam.ac.uk).

Table S1. Crystal data and structure refinement for compounds $\mathbf{1 b}$ and $\mathbf{1 d}$.

|  | Compound 1b | Compound 1d |
| :---: | :---: | :---: |
| Empirical formula | $\mathrm{C}_{25} \mathrm{H}_{16} \mathrm{~N}_{3} \mathrm{O}_{2} \mathrm{Cl}_{3}$ | $\mathrm{C}_{34} \mathrm{H}_{28} \mathrm{~N}_{4} \mathrm{O}_{4}$ |
