## 1. Detailed describe and explanation of the falling ball method

A falling ball viscosity apparatus is shown in **Fig. S1**. The instrument includes an aluminum ball, a tungsten wire, two ceramic pulleys, a regulating weight and a ruler. The diameter of the aluminum ball is  $1.9 \times 10^{-2}$  meters. The diameter of the tungsten wire is  $3 \times 10^{-5}$  meters. The inner diameter of the ceramic pulley is  $3 \times 10^{-3}$  meters. Before measurement, the aluminum ball was immersed in the pitch melt and the regulating weight was held. After release the movement of the regulating weight was recorded by video. The displacement with time was read out by analyzing the video and the moving speeds were calculated.

Fig. S1. The falling ball viscosity apparatus.

The viscosity of the pitch can be regressed by simulating the movement of the ball in consideration of the force analysis. Take the displacement to be x in time t, and set u is the dropping speed of the ball, then according to the force analysis of the ball,

$$\frac{d^2x}{dt^2} = \frac{(m_1 - m_2)g - F_L - F_1 - F_2 - F_i}{m_1 + m_2}$$
(1)  
$$u = \frac{dx}{dt}$$
(2)

where,  $m_1$  and  $m_2$  are the masses of the ball and the regulating weight, g is the gravitational acceleration,  $F_L$  and  $F_I$  are the buoyancy force and the viscous resistance

that are given to the ball by the pitch melt.  $F_2$  is the frictional drag that is given to the tungsten wire by the pitch melt.  $F_i$  is the friction force of the pulley bock. The mass of the tungsten wire and its buoyancy given by the pitch melt are neglected.

Set the radius of the ball as  $r_1$  and the density of the pitch melt is  $\rho$ , so the buoyancy on the ball is

$$F_L = \frac{4}{3}\pi r_1^3 \rho \tag{3}$$

Set the friction coefficient of the ball with the pitch melt and projected area of the ball along the movement direction as  $\zeta$  and A, and  $u_1$  as the ball's speed relative to the pitch melt, so according to the equation about ball dropping in a liquid, the viscous resistance is

$$F_1 = \zeta A \frac{\rho u_1^2}{2}$$

where calculation of the friction coefficient depends on the Reynolds numbers Re,

according to  $\zeta = \frac{18.5}{Re^{0.6}}$  or  $\zeta = \frac{24}{Re}$  when 1 < Re < 1000 and Re < 1 respectively. Setting the viscosity of the pitch melt as  $\mu$ , the Reynolds numbers is

$$Re = \frac{2r_1u_1\rho}{\mu}$$

Setting *u* to be the speed of the ball, when the ball dropping, the isometric pitch melt is pushed upside, therefore the ball's speed relative to the pitch melt should be corrected by the following equation.

0

$$u_1 = u \frac{R^2}{R^2 - r_1^2}$$

where R is the inner diameter of the reaction.

So, when 1<*Re*<1000,

$$F_{1} = \frac{18.5}{\left(\frac{2r_{1}u\rho}{\mu}\right)^{0.6}\left(\frac{R^{2}}{R^{2} - r_{1}^{2}}\right)^{1.2}} \cdot \pi r_{1}^{2} \cdot \frac{\rho u^{2}}{2}\left(\frac{R^{2}}{R^{2} - r_{1}^{2}}\right)^{2}$$
(4)

when *Re*<1,

$$F_{1} = \frac{24}{\frac{2r_{1}u\rho}{\mu}} \cdot \frac{R^{2}}{R^{2} - r_{1}^{2}} \cdot \pi r_{1}^{2} \cdot \frac{\rho u^{2}}{2} (\frac{R^{2}}{R^{2} - r_{1}^{2}})^{2}$$
(5)

The viscous resistance given to the tungsten wire by the pitch melt increases with its immersed length, and can be calculated as follows according to the basic formula

$$F_2 = 2\pi r_2 x \cdot \mu \cdot \frac{du}{dr}$$

where,  $r_2$  is the radius of the tungsten wire. The velocity gradient can be simplified to the following equation because the diameter of the tungsten wire is much smaller than that of the reactor inner referred to the literature<sup>[S1]</sup>.

$$\frac{du}{dr} = \frac{u}{r_2 ln\left(\frac{R}{r_2}\right)}$$

So, the viscous resistance given to the tungsten wire by the pitch melt can be calculated by the following equation.

$$F_2 = 2\pi x \cdot \mu \cdot \frac{u}{ln\left(\frac{R}{r_2}\right)} \tag{6}$$

The friction force  $F_i$  is proportional to the press force exerted on the pulleys by the tungsten wire. However, the friction coefficient was found varying with the press force, so a formula must be set up. **Fig. S2** is the relationship between the friction coefficient and the press force exerted by the tungsten obtained through hanging different weights. The curve is identically regressed to the empirical formula.

$$K_{fi} = 0.3288 * e^{-\frac{F_p}{0.0342}} + 0.0598$$

where,  $K_{fi}$  is the friction coefficient,  $F_p$  is the total press force on the pulleys.

Fig. S2. Regressed curve of the friction coefficient of the pulley block with the total press force.

Because the total force  $F_p = (m_1 + m_2)g - F_L - F_I - F_2$ , therefore, the friction force  $F_i$  can be calculated by the following equation.

Fi  
= 
$$\left(0.3288 * e^{-\frac{(m_1 + m_2)g - F_L - F_1 - F_2}{0.0342}} + 0.0598\right) * ((m_1 + m_2)g - F_L - F_1)$$

(7)

A series of data about the distance and time of the falling ball can be obtained by experiment. Then from equation (1) to (7), the viscosity of the pitch melts can be solved by Ordinary Differential Equation (ODE) fitting with MATLAB, as shown in **Fig. S3**.
