

## Supplementary Information

### Materials and methods

#### Chemicals

Commercial iridium oxide hydrate catalyst ( $\text{IrO}_2 \cdot x\text{H}_2\text{O}$ , 99.95% trace metals), titanium carbide (nanopowder, particle size  $< 200$  nm), ruthenium(IV) oxide ( $\text{RuO}_2$ , 99.95% trace metals), ruthenium black, perchloric acid ( $\text{HClO}_4$ , 99.99% trace metal basis), iridium(III) chloride ( $\text{IrCl}_3 \cdot x\text{H}_2\text{O}$ , 99.9% trace metal basis), ruthenium(III) chloride ( $\text{RuCl}_3$ , Ru content 45-55 wt.%), potassium hydroxide (KOH,  $\geq 99.99\%$  trace metals basis), isopropyl alcohol (IPA,  $\geq 99.5$  wt.%), ethylene glycol (ReagentPlus<sup>®</sup>,  $\geq 99$  wt.%), copper sulfate ( $\text{CuSO}_4$ , ReagentPlus<sup>®</sup>,  $\geq 99$  wt.%), and sulfuric acid ( $\text{H}_2\text{SO}_4$ , ACS reagent, 95.0-98.0 wt.%) were purchased from Sigma-Aldrich. Iridium black (99.95% trace metals basis) was obtained from Alfa Aesar. Nafion dispersion (5 wt.%, alcohol-based) was purchased from Fuel Cell Store (Texas, USA). All chemicals were used without further purification. Ultrapure water (18 M $\Omega$ /cm) used in all experiments was prepared by the Millipore system.

#### Synthesis of $\text{Ir}_x\text{Ru}_y/\text{TiC}$

In a typical synthesis, iridium(III) chloride hydrate, ruthenium(III) chloride, and 200 mg of TiC were dissolved in 50 mL ethylene glycol at room temperature in a beaker. The loading of Ir and Ru was set at 20 wt. % relative to TiC. The obtained mixture was stirred for 1 hour at a rotation speed of 800 rpm to form a uniform suspension. Subsequently, the suspension was heated over an oil bath filled with silicon oil for 5 hours at the same rotating speed and 170 °C. After the reaction, the product was washed with deionized water 5 times and harvested using a centrifuge, and then dried in a vacuum oven.

#### Physical characterization

X-ray diffraction (XRD) was performed on a Shimadzu XRD-6000 with Cu K $\alpha$  radiation (40 kV, 30 mA,  $\lambda = 1.5418\text{\AA}$ ). The morphological and structural information was examined by a JEOL JEMARM200F scanning transmission electron microscopy (STEM) with sub-angstrom-resolution (0.08 nm) equipped with an energy-dispersive X-ray spectroscopy (EDX) analyzer. Atomic resolution images were taken in the high-angle annular dark-field (HAADF-STEM) mode. Electron energy loss spectroscopy (EELS) spectra were collected using a Gatan imaging filter (Quantum 965).

X-ray absorption spectroscopy (XAS) was carried out in total-fluorescence-yield mode at ambient air with beamline of BL-12B2 ( $25 < E < 70$  keV, with a resolution of  $\Delta E/E \sim 10^{-4}$ ) in Spring-8, HARSI, Japan. X-ray absorption near-edge structure (XANES) and extended X-ray absorption fine structure

(EXAFS) were performed to examine the valence state and coordination environment. Energy scan range between 11,000 and 12,000 eV was used to measure the Ir spectra, and energy scan range between 21,800 and 22,800 eV was used to measure the Ru spectra. The wavelet transform of the EXAFS spectra was based on the Continuous Cauchy Wavelet Transform (CCWT) modulus.<sup>1,2</sup> The coordination fitting of EXAFS spectra was conducted by Athena software using the standard crystal structure file from American Mineralogist Crystal Structure Database.

### Electrochemical measurements

The OER performance of the as-prepared samples was measured in 0.1 M ultrapure HClO<sub>4</sub> solution based on a three-electrode configuration. A leak-free saturated calomel electrode (SCE) was used as the reference electrode and a Pt plate was used as the counter electrode. The electrochemical performance was examined on a glassy carbon rotating disk electrode (RDE, disk diameter = 5.5 mm, Pine Research Instrument). All electrochemical data were collected on a CHI 760e electrochemical workstation (CHI instrument). The loading amount of catalyst was kept as 100 μg/cm<sup>2</sup>. The OER polarization curves were measured in N<sub>2</sub> saturated 0.1 M ultrapure HClO<sub>4</sub> solution at a scan rate of 5 mV/s with a rotating speed of 1600 rpm. The current density was normalized to the electrode area of glassy carbon (GC). The stability tests were performed in 0.1 M HClO<sub>4</sub> solution at 10 mA/cm<sup>2</sup>.

The surface structure of Ir<sub>x</sub>Ru<sub>y</sub>/TiC after OER was characterized by electrochemical Cu stripping. The Ir<sub>x</sub>Ru<sub>y</sub>/TiC sample was first electrochemically reduced in 0.1 M H<sub>2</sub>SO<sub>4</sub> solution at 0.02 V vs. SCE and then moved into a mixed solution containing 0.05 M H<sub>2</sub>SO<sub>4</sub> and 1 mM CuSO<sub>4</sub> with potential held at 0.02 V vs. SCE for 100 s.<sup>2</sup> Afterwards, the catalyst was transferred into a Cu-free electrolyte and a cyclic voltammetry measurement was conducted.

### Computational details

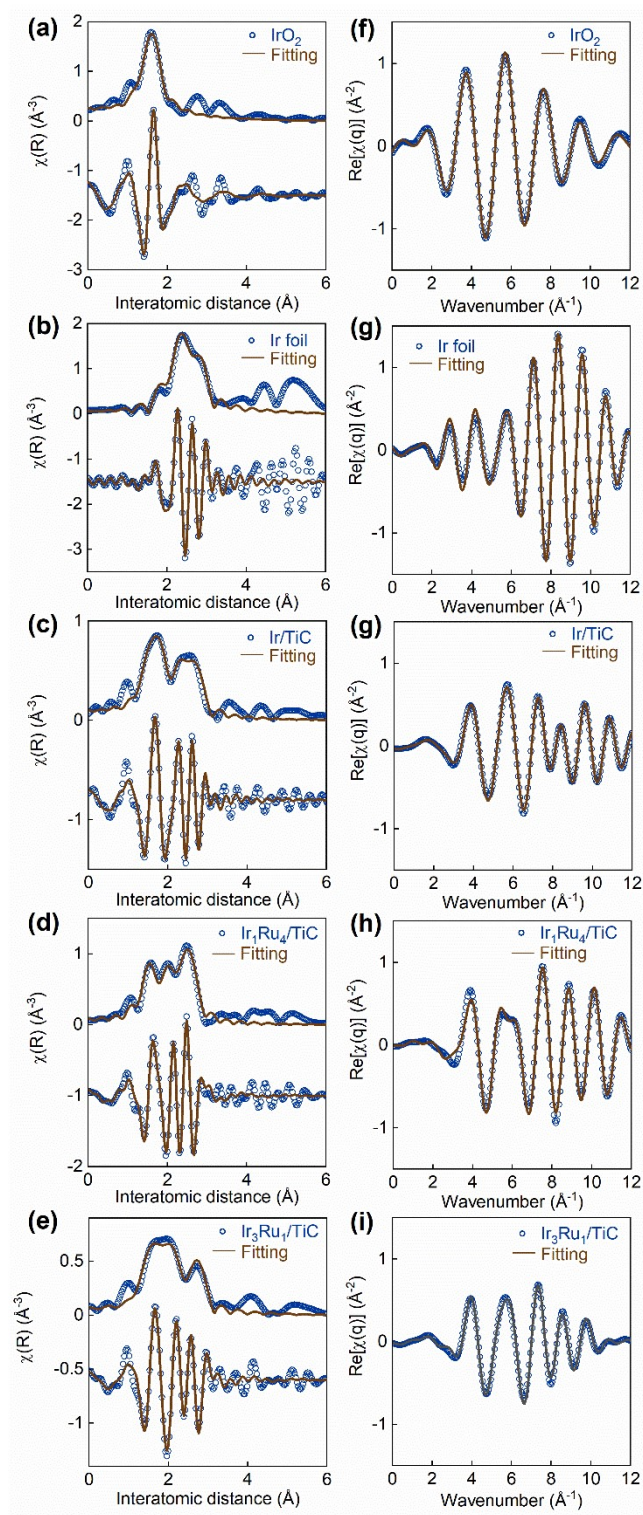

A 2×2×1 supercell of bulk Ru with different ratios of Ir was used to model IrRu alloy. The calculated bulk structures and lattice parameters are shown in **Table S4**. Then the (101) surface of the expanded 2×2×2 supercell was built to simulate the IrRu alloy before electrocatalysis. The selected parameters of (101)-surface structures for Ir<sub>1</sub>Ru<sub>3</sub>, Ir<sub>1</sub>Ru<sub>1</sub>, Ir<sub>3</sub>Ru<sub>1</sub> and Ir are listed in **Table S5**. The slab consists of four atomic layers, where the bottom two were frozen while the remaining layers were allowed to relax. As shown in the experimental results (Figure 2e, S5 and Table S3), the surface was covered with Ir oxide while surface Ru had been etched into the solution during OER. Therefore, we built an IrO<sub>x</sub> cluster anchored on the (101)-surface of Ir<sub>x</sub>Ru<sub>y</sub> alloy with different Ir/Ru ratios to simulate the real active surfaces, as shown in **Figure S8**. All the supercell slabs were repeated periodically with a 15 Å vacuum layer between the images in the direction of the surface normal.

All DFT calculations were performed by using the spin-polarized Kohn-Sham formalism with the generalized gradient approximation (GGA) of Perdew-Burke-Ernzerhof (PBE),<sup>3</sup> as implemented in the Vienna Ab-initio Simulation Package (VASP version 5.4.4).<sup>4</sup> The valence electronic states of all atoms were expanded in a plane-wave basis set with a cutoff energy of 400 eV, and a Monkhorst-Pack  $3\times 3\times 1$  grid was used to sample the Brillouin zone. Atomic positions were optimized by using a conjugate gradient algorithm until the forces were less than  $0.03 \text{ eV \AA}^{-1}$  for all intermediates. Vibrational frequency analysis was performed and Gibbs free energy corrections were calculated by using VASPKIT 1.2.5.<sup>5</sup>

## Supplementary figures
