1 General Experimental

Unless otherwise mentioned, all materials were commercially obtained and used without further purification. imidazoheterocycles (**3**)¹ were synthesized according to previously described methods. The ¹H NMR, ¹³C NMR, and ¹⁹F NMR spectra were recorded at 500 MHz, 126 MHz, 471 MHz, respectively, on a Bruker AM500 MHz with chemical shift values in ppm relative to TMS (δ H 0.00 and δ C 0.0) as internal standard. The coupling constants J , are reported in Hertz (Hz). All melting points were determined on a SGW X-4A melting point instrument without correction. High-resolution mass spectra (HRMS) were recorded on Q-Exactive plus Orbitrap (ESI) or HP-5989A instrument.. Infrared spectra (IR) were recorded on Spectrum TWO. Reactions were monitored by thin layer chromatography (TLC), on glass plates coated with silica gel with Fluorescent indicator (Huanghai, HSGF254) and visualized with UV light at 254 nm. Flash chromatography was performed on silica gel (Huanghai, 300-400) using petroleum ether (PE)-ethyl acetate (EA) as eluent. The structure of product **3c** (CCDC file number 2181031) was further confirmed by X-ray diffraction collected on a diffractometer with graphite-monochromated Cu K α radiation.

4 Control experiments

Treatment of **1a**, **2a**, and **I₂** in DMF afforded intermediate **11** in 93% yield. The addition of NaOAc·3H₂O transformed **11** into ketosulfone **12** (Figure S1a). The reaction of **7a** and **8a** without Fe(acac)₃ afforded **12** at a 63% yield (Figure S1b). Furthermore, the combination reaction of **12** and **3a** at 140 °C with CoCl₂·6H₂O or Fe(acac)₃ provided **4a** with yields of 91% and 88%, respectively (Figure S1c), indicating that **11** and **12** could be plausible reaction intermediates.

6 X-ray diffraction analysis of compound 4j

Sample preparation:

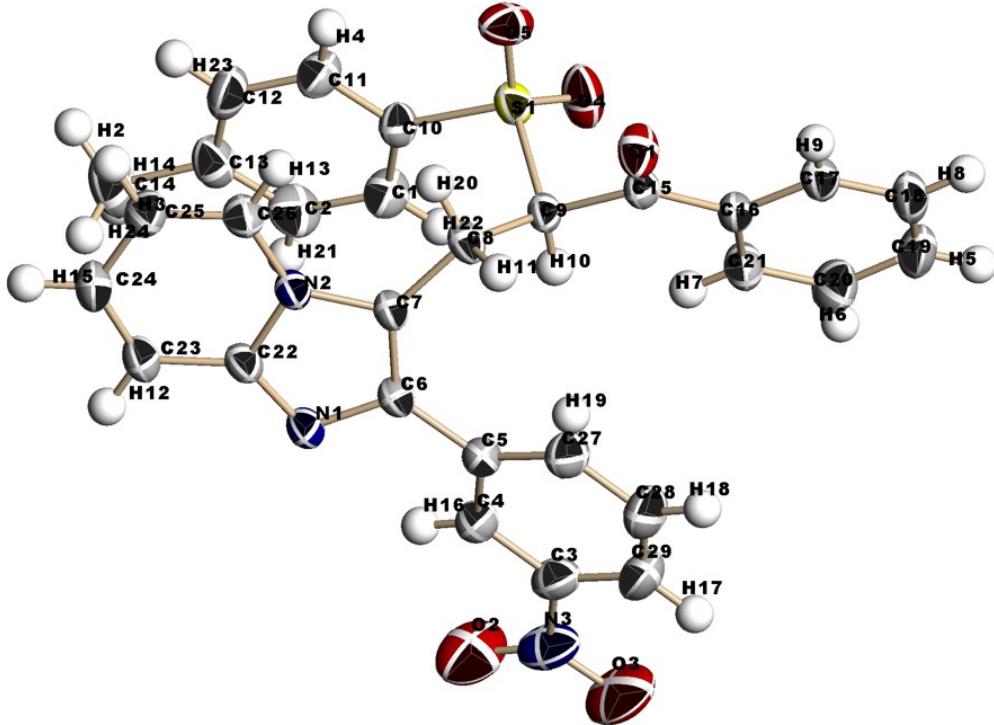

The method for crystal growth is slow volatilization using petroleum ether (PE)-ethyl acetate (EA) mixture as a solvent.

Crystal measurement for compound 4j:

A specimen of $\text{C}_{29}\text{H}_{23}\text{N}_3\text{O}_5\text{S}$, approximate dimensions 0.150 mm x 0.200 mm x 0.250 mm, was used for the X-ray crystallographic analysis. The X-ray intensity data were measured (λ = 0.71073 Å).

The integration of the data using a triclinic unit cell yielded a total of 31127 reflections to a maximum θ angle of 27.55° (0.77 Å resolution), of which 5555 were independent (average redundancy 5.603, completeness = 97.9%, R_{int} = 6.02%, R_{sig} = 4.41%) and 4432 (79.78%) were greater than $2\sigma(F^2)$. The final cell constants of a = 7.1153(4) Å, b = 12.1904(7) Å, c = 14.8931(8) Å, α = 79.211(2)°, β = 77.257(2)°, γ = 80.078(2)°, volume = 1226.09(12) Å³, are based upon the refinement of the XYZ-centroids of reflections above 20 $\sigma(I)$. The calculated minimum and maximum transmission coefficients (based on crystal size) are 0.9560 and 0.9740.

The structure was solved and refined using the Bruker SHELXTL Software Package, using the space group P -1, with Z = 2 for the formula unit, $\text{C}_{29}\text{H}_{23}\text{N}_3\text{O}_5\text{S}$. The final anisotropic full-matrix least-squares refinement on F^2 with 344 variables converged at $R1$ = 4.23%, for the observed data and $wR2$ = 11.50% for all data. The goodness-of-fit was 1.030. The largest peak in the final difference electron density synthesis was 0.345 e⁻/Å³ and the largest hole was -0.380 e⁻/Å³ with an RMS deviation of 0.054 e⁻/Å³. On the basis of the final model, the calculated density was 1.424 g/cm³ and $F(000)$, 548 e⁻.

Plots are drawn at 50% probability level.
