Isolated phenanthroline and N-heterocyclic rings

The molecular properties of isolated phenanthroline and five-membered N-heterocyclic rings R₁~R₈ were evaluated by using electronic structure calculations. Several indicators are used to described the molecular properties of Ph and R₁~R₈, including electrostatic potential (ESP), natural atomic charges of coordinating N atoms, HOMO energy, and protonation energy, which are calculated at the PBE0/6-311G(d) level and listed in **Table S1**. It is notable that R₁~R₃ are constitutional isomers, R₂(R₃) are more stable than R₁ by 9.98 kcal/mol, and that R₄~R₈ are also constitutional isomers, among which R₇(R₈) is the most stable, and from R₄ to R₅ to R₆ to R₇(R₈) their energies go down successively by 5.33, 4.71 and 7.53 kcal/mol, respectively. Thus, the N-N and N-N-N structures are not conducive to molecular stabilization. Since the bonding interaction between the *f*-element and ligand is mainly ionic in nature, the ESP of the ligand can be used to measure coordination ability of the ligand with the lanthanides and actinides. The ESP values of the ligand are mapped onto electron density isosurface (0.002e/Å³) by various colors in **Fig.S1**. The ESP minimum of R₁~R₈ is located at the site of the N atom, and the ESP minimum of Ph is situated at the intersection of the two symmetry axes of the two pyridines through the N atom, as shown in **Fig.S1**, which are deemed as the coordination sites with the metal. The bidentate ligand Ph has much more negative ESP minimum than the monodentate ligand R₁~R₈, owing to the synergistic effect between the two pyridine N atoms, so its coordination capacity is certainly much stronger than R₁~R₈. And the coordination ability of the monodentate ligand R₁~R₈ reduces according to the order of R₆ > R₂(R₃) > R₄ > R₇(R₈)> R₁ > R₅, as shown by the ESP minima in **Table S1**. The charge on the coordinated N atom is the highest in R₇(R₈), followed by R₂(R₃), the third is Ph, and the charges on the coordinated N atom of the other ligands are close to each other. There is no apparent relationship between the ESP and *q*(N). ESP is a physical observable and determined by the overall charge distribution of the molecule and reflects the ability of a molecule participating in electrostatic interaction, while the atomic charges have none of these properties.

The extraction process of lanthanides and actinides is carried out under acidic conditions, the weakly alkaline extractants are easy to protonate. Protonation free energy ΔG was evaluated for the reaction equation $L + [H_3O]^+ = [LH]^+ + H_2O$ in aqueous phase, and listed in **Table S1**. It can be observed that the N atoms on Ph are more prone to protonation than $R_1 \sim R_8$. The protonation energy of the coordination N atoms on R_1 to R_8 is very close, so their protonation tendency is similar. In general, these monodentate ligands $R_1 \sim R_8$ and bidentate ligand Ph have a high protonation tendency.

The most important indicator reflecting property of the ligands is the interaction energy between the ligands and the Am(III) and Eu(III) ions in their complexes. In the gas phase, the 1:1 complexes of the monodentate ligands $R_1 \sim R_8$ with Am/Eu are unstable, so we calculate the 1:2 complexes $R_iMR_i^{3+}$ formed by M^{3+} with two identical ring R_i ($i = 1 \sim 8$). The complexes $R_iMR_i^{3+}$ have *cis-trans* isomers, here we only consider the *trans*-isomers. The geometry structures optimized for MPh^{3+} and $R_iMR_i^{3+}$ at the PBE0/6-311G(d)-RECP level are shown in **Fig.S2**. The interaction energy in $R_iMR_i^{3+}$ is $\Delta E = [E(R_iMR_i^{3+}) - E(M^{3+}) - 2E(R_i)]/2$. The calculated energy for each M-N interaction is about $128 \sim 200$ kcal/mol, as shown in **Table S2**. It is found that $R_2(R_3)$ has the most strong interaction with both Am(III) and Eu(III) ions, the interaction strength of these ligands with Am and Eu follows the same order $R_2(R_3) > R_6 > R_1 > R_4 > R_7(R_8) > R_5$. It is notable that the Am-N bond length is significantly smaller than the corresponding Eu-N bond length and the Am-N bond order (WBI values) is also larger than that of the corresponding Eu-N bond, while the interaction energy of Am(III) ion with the N-donor is smaller than that of Eu(III) ion by about 20kcal/mol for R_1 to R_4 , or 17kcal/mol for R_6 to R_8 . This inconsistency between bond length, bond order, and interaction energy will be explained later.

It has been shown that the solvation has significant effects on the interaction of lanthanides and actinides with ligand. Here we consider two solvents, water and n-Octanol, for the 1:1 complexes MR_i^{3+} of the Am(III) and Eu(III) with the monodentate ligands R_i ($i = 1 \sim 8$). The model chemistry also has great influence on the prediction of the metal-ligand interaction, here we consider three quantum chemistry theoretical methods, DFT methods with quasi-relativistic effective core potentials (QRECP), ZORA (Zero Order Regular Approximation) and DKH (Douglas Kroll Hess) methods.

In the DFT calculation with QRECP, the functionals also have significant effects on the calculated results, so we take a series of functionals to perform DFT calculation, including the exchange- correlation functionals BP86 and PBE, and the hybridized functionals TPSSH, B3LYP, PBE0 and M06-2X. For the 1:1 complexes MR_i^{3+} ($i = 1 \sim 8$) of the metal with the monodentate ligands R_i , we consider two structures, one is the global minima, the other is the constrained minima, thus the minima with the M-N-C angle constrained to approximate the M^{3+} location observed in the complex $M(PhR_i)^{3+}$ of M^{3+} with the tridentate ligand PhR_i . For MR_6^{3+} the two structures have obvious difference, while for the other complexes MR_i^{3+} ($i \neq 6$) the two structures have small difference. For the global minima, the M-N bond length and the interaction energy between M^{3+} and R_i in the optimized structure by the various functionals in the aqueous phase were listed in **Tables S3 and S4** and shown in **Fig.S3**. For the constrained minima, we optimized the structures of the complexes MR_i^{3+} ($i = 1 \sim 8$) in the aqueous phase and n-octanol phase using DFT method with various functionals, the results of the aqueous phase are shown in **Fig.S4** and in **Tables S5 and S6**, and the results of the n-octanol phase are shown in **Fig.S5** and in **Tables S7 and S8**.

We first consider the results of the **constrained** minima in the **aqueous** phase. For the Am complexes AmR_i^{3+} , the bond lengths and bonding energies given by various functionals are quite consistent with the ESP of the ligands, thus AmR_2^{3+} and AmR_6^{3+} have the shortest Am-N bond length and the greatest bonding energy, while AmR_5^{3+} has the longest Am-N bond length and the least bonding energy, as shown in **Fig.S4** and **Tables S5-S6**. Moreover the variation law of the bond length and bonding

energy across the series of $R_1 \sim R_8$ are also consistent for various functionals, except that B3LYP gives a quite large Am-N bond length for AmR_5^{3+} . For the Eu complexes EuR_i^{3+} , there are some obvious difference from the AmR_i^{3+} complexes. The variation laws of the bonding energies given by various functionals are consistent with each other, EuR_2^{3+} has the greatest bonding energy and EuR_5^{3+} has the least bonding energy, while the bonding energy of EuR_6^{3+} is always less than that of EuR_1^{3+} for the various functionals except for PBE0. The Eu-N bond lengths given by various functionals are very inconsistent, only the BP86 and PBE functionals produce Eu-N bond lengths consistent with the ESP of the ligands, all the hybridized functionals can not give bond lengths consistent with ESP. It is worth noting that although the bonding energy in the solution phase is much smaller than that in the gas phase due to the solvent effect, in the solution phase the bonding energy of Am-ligand bond is still less than that of Eu-ligand bond, similar to the gas phase. This should be a general feature of DFT calculations with quasi-relativistic effective potentials, regardless of the functional used. For the results of the global minima of the aqueous phase in **Fig.S3** and in **Tables S3 and S4**, except that the bond lengths have some inconsistent with the results of the constrained minima in the aqueous phase, the bonding energies of the global minima and constrained minima are consistent with each other. The influence of solvent effect on bond length and bond energy is obvious. For the constrained minima, although the results of the n-octanol phase have much similar characters to the results of the aqueous phase, we can still observe their obvious difference. For example, the consistency between the different functionals in the n-octanol phase gets worse, and the bond energy of the n-octanol phase is more than 10kcal/mol higher than that of the aqueous phase, as shown in **Fig.S5 and in Tables S5 and S6**.

That the Am-ligand bonding energy predicted by DFT-RECP method is smaller than the Eu-ligand bond energy is quite unreasonable and inconsistent with the bond lengths, bond order and electron density topological properties (QTAIM parameters). To improve this situation, we perform relativistic quantum chemistry calculations using the ZORA and DKH methods. The calculated bond lengths and bonding energies of the Am-N and Eu-N bonds are shown in **Tables S9 and S10**, and also plotted in **Fig.S6**, and the corresponding QTAIM parameters are listed in **Table S11**. For comparison purposes, we have also included the results of DFT-RECP with PBE0 functional in these graphs and tables. The ZORA and DKH methods predicted much larger bonding energy than DFT-RECP-PBE0 method. For the Eu complexes EuR_i^{3+} , the DKH bonding energy is very close to the ZORA bonding energy, the former is only 2kcal/mol less than the later. However, for the Am complexes AmR_i^{3+} , the DKH bonding energy is much larger than the ZORA bonding energy, by at least 200 kcal/mol. It can be seen that the ZORA bonding energy of the Am-ligand bond is still less than the ZORA bonding energy of the Eu-ligand bond, similar to the DFT-RECP method, while the Am-ligand bonding energy predicted by DKH method is much larger than the corresponding Eu-ligand bonding energy. Therefore, DKH method predicted bonding energy consistent with bond length, while the ZORA and DFT-RECP methods fail to do this. From **Fig.S6(a) and (c)** and **Table S9**, we can see that the ZORA and DKH methods predicted much shorter Am-N bond than the DFT-RECP method except for the AmR_2^{3+} complex, while the Eu-N bond length predicted by ZORA and DKH methods is larger than that by DFT-RECP method except for the EuR_1^{3+} complex. It is worth noting that the Eu-N bond lengths predicted by ZORA and DKH are very close to each other, while the Am-N bond length predicted by DKH is smaller than that predicted by ZORA. So we note that there are significant differences in the treatment of Am and Eu by ZORA and DKH methods.

The QTAIM parameters, ρ and $\nabla^2\rho$ and H at the Am-N BCPs calculated by the ZORA and DKH methods, are much larger than those by DFT-RECP method, and the ZORA and DKH methods give very

close results, as shown in **Table S11**. The ZORA and DKH methods predict stronger and more covalent Am-N bond than the DFT-RECP method. However, for the Eu-N bond, the ZORA and DKH give a BCP electron density something less than that of DFT-RECP. Anyway, the three methods are consistent in predicting the nature of Am-N and Eu-N bonds, that is, both Am-N and Eu-N bonds are mainly ionic in nature, and the covalence of Am-N bond is higher than that of Eu-N bond.

Effects of spin-orbit coupling on compounds

To understand the impact of spin-orbit coupling in the interaction between Americium and the ligands, optimizations of the $\text{AmR}_4\text{PhR}_4(\text{NO}_3)_3$ compound were performed at the PBE0/ZORA theoretical level considering both spin-orbit coupling (SOC) and non-spin-orbit coupling (NOSOC) interactions. The obtained N-Am bond lengths, QTAIM properties, and Mayer bond orders are summarized in the **Table S12**. Notably, considering SOC interactions resulted in an average bond length for N-Am that was shorter by 0.0006 Å compared to when SOC interactions were not considered. However, the differences in QTAIM properties such as ρ , $\nabla^2\rho$, $H(r)$, and Mayer bond orders were not significantly distinct. Overall, the covalency of N-Am under SOC consideration appeared slightly higher than without SOC, although this increase in covalency was not distinctly pronounced. Additionally, single-point energies $E(\text{a.u.})$ and free energies $G(\text{a.u.})$ were calculated for the $\text{AmR}_4\text{PhR}_4(\text{NO}_3)_3$ compound under both spin-orbit coupling (SOC) and non-spin-orbit coupling (NOSOC) interactions (**Table S13**). The energy difference (ΔE in kcal/mol) and free energy difference (ΔG in kcal/mol) indicate that spin-orbit interactions contribute minimally to energy and Gibbs free energy calculations. Kaneko et al. also confirmed the negligible contribution of spin-orbit coupling effects to Gibbs energy calculations for complex formation reactions (less than 0.005 kcal/mol) (Inorg. Chem. 2018, 57, 14513-14523)

The constrained minima of the MR_i^{3+} complexes ($i = 1\sim 8$) with the M-N-C angle constrained to approximate the M^{3+} location observed in the complex $\text{M}(\text{PhR}_i)^{3+}$ calculated by using the PBE0/ZORA/DKH/6-311G(d)-RECP methods and the CPCM solvation model in aqueous phase
