Experimental Section

Electrochemical measurements of nitrate reduction reaction (NO₃RR)

Determination of ion concentration

The ultraviolet-visible (UV-Vis) spectrophotometer was used to detect the ion concentration of pre- and post-tested electrolytes after diluting to appropriate concentration to match the range of calibration curves. The specific test methods are as follows:

Determination of ammonia

Ammonia-N was determined using salicylic acid-potassium sodium tartrate chromogenic reagent as the color reagent. First, a certain amount of electrolyte was taken out from the electrolytic cell and diluted to 2 mL to the detection concentration range. Next, 2 mL salicylic acid-potassium sodium tartrate chromogenic reagent was added into the diluted electrolyte, and mixed thoroughly. Then, 0.05 mL sodium hypochlorite and 0.2 mL sodium nitroprusside solution were put into the above solution. The absorption intensity at a wavelength of 655 nm was recorded. The concentration-absorbance curve was calibrated using a series of standard ammonium chloride solutions and the ammonium chloride crystal was dried at 108°C for 2 h in advance.

Determination of NO₃⁻

Firstly, a certain amount of electrolyte was taken out from the electrolytic cell and diluted to 2 mL. Then, 0.1 mL 1 M HCl and 0.01 mL 0.8 wt% sulfamic acid solution

were added into the aforementioned solution. The absorption spectrum was measured using an UV-Vis spectrophotometer and the absorption intensities at a wavelength of 220 and 275 were recorded. The final absorbance is calculated using the following formula: $A = A_{220nm} - 2A_{275nm}$. The concentration-absorbance curve was calibrated using a series of standard potassium nitrate solutions.

Determination of NO₂⁻

Color reagent was a mixture of p-aminobenzenesulfonamide (0.1 g), N-(1-naphthyl) ethylenediamine dihydrochloride (0.01 g), deionized water (5 mL) and phosphoric acid (0.294 mL, $\rho = 1.685$ g mL⁻¹). First, the electrolyte was diluted to the detection concentration range. Subsequently, 1 mL color reagent was added into the diluted electrolyte in a colorimetric cuvette. After shaking and standing for 10 minutes, the absorbance measurements were performed at wavelength of 540 nm. The obtained calibration curve was used to calculate the nitrite concentration.

Determination of N₂H₄

First, a certain amount of electrolyte was taken out from the electrolytic cell and diluted to 2 mL to the detection concentration range. Subsequently, 1 mL color reagent was added into the diluted electrolyte in a colorimetric cuvette. Color reagent was a mixture of anhydrous ethanol (50 ml), HCl (5 ml) and $p-C_9H_{11}NO$ (1 g). The absorption intensity at a wavelength of 455 nm was recorded after standing for 20 min.

Isotope Labeling Experiments

K¹⁵NO₃ was used as the feeding N-source to perform the isotopic labeling nitrate reduction experiments to verify the source of ammonia. 0.1 M PBS was used as the

electrolyte, and $K^{15}NO_3$ with a concentration of 0.1 M $^{15}NO_3^-$ was added into the cathode compartment as the reactant. After electroreduction, electrolyte with obtained $^{15}NH_4^+$ was taken out and the pH value was adjusted to be weak acidic with 1 M HCl for qualitative analysis by ¹H NMR (600 MHz) with external standards of maleic acid.
