## Experimental section

## (a) General Procedure:

All reactions were conducted under an ozone atmosphere using oven-dried glass wares. A 100 W Hg lamp was used as a light source without any filter. Ozone was generated by an ozone generator (C-labsky series, model no. c-1010-DT)) using pure oxygen gas as the source of oxygen with a flow rate of 0.45 $\mathrm{mL} / \mathrm{min}$. Starting materials (Aldrich) are commercially available and were used as received. NMR spectra were recorded in $\mathrm{CDCl}_{3}$, DMSO or $\mathrm{CDCl}_{3}$-DMSO mixture. ${ }^{1} \mathrm{H} \mathrm{NMR}$ at 600 MHz and ${ }^{13} \mathrm{C} \mathrm{NMR}$ at 150 MHz were used to determine the structures of products. Data were reported as: $\mathrm{s}=$ singlet, $\mathrm{d}=$ doublet, $\mathrm{t}=$ triplet, $\mathrm{q}=$ quartet, $\mathrm{m}=$ multiplet, $\mathrm{b}=$ broad .

## (b) General procedure for dechlorination of chlorobenzene to oxalic acid:

A dry test tube of 20 mL capacity was charged with chlorobenzene $(5 \mathrm{~mL})$ mixed with 6 mL of $\mathrm{CH}_{3} \mathrm{CN}-\mathrm{H}_{2} \mathrm{O}$ (4:2) solvent system with neutral medium and equipped with a Teflon septum and a magnetic stirrer bar. Ozone gas was bubbled into the chlorobenzene solution and simultaneously irradiated under a $100 \mathrm{~W} \mathrm{Hg} \operatorname{lamp}\left(200 \mathrm{~mW} / \mathrm{cm}^{2}\right.$ at 310 nm$)$ for 10 h at room temperature. Upon irradiation, white solid was slowly formed and precipitated. The white solid was further dispersed in ethyl acetate-hexane (80:20) solution. Pure oxalic acid solid was obtained by centrifugation. The structure of the solid product oxalic acid was determined by ${ }^{1} \mathrm{H}$ NMR, ${ }^{13} \mathrm{C}$ NMR and confirmed by x-ray crystallography. All experiments were repeated at least 3 times.

## Procedure for determination of conversion, and mass balance ${ }^{1}$.

After ozone-UV irradiation, a known amount (in mole) of external standard, 1,4-dicyanobenzene, was added to the final crude products solution. Once the external standard was added, the molar ratios of all products relative to the external standard in the final solution are fixed irrespective of the later experimental procedure. Then, the absolute amounts of all products in the final solution can be determined by multiplication of the relative molar ratios of all crude products to the external standard (determined by ${ }^{1} \mathrm{H}$ NMR peak area ratio) with the mole of the external standard added. The mass balance was determined by the sum of all products (in moles, including unreacted starting substrate) divided by the initial mole of starting material. The conversion percentage was determined by the total moles of all crude products divided by the initial mole of the starting material.

## EPR measurements of hydroxyl radicals ${ }^{1,2}$ :

EPR spectra ( X band, 9.8 GHz , room temperature) were taken from samples of cyclopentylchloride ( $95 \%$ ) with $5 \%$ of water and ACN mixture under photoirradiation or dark condition in the presence a radical trapping reagent, 5,5-dimethyl-1-pyrroline-N-oxide (DMPO, $2.5 \times 10^{-2} \mathrm{M}$ ). The parameters used in the simulation are the followings: $\mathrm{g}=2.0073$, coupling constant $\mathrm{A}_{\mathrm{N}}=7.2 \mathrm{G}(1 \mathrm{~N})$ and $\mathrm{A}_{\mathrm{rH}}=4.1 \mathrm{G}(2 \mathrm{H})$. All measurements were done at room temperature. By using DMPO as a spin trapping reagent, we have detected the presence of hydroxyl radical (see the EPR spectra shown below in Fig. S1) in both dark and photo conditions in the case of chlorobenzene-neutral water-ozone system. The observed EPR spectrum for both conditions is the same as those reported in the literature.

Figure S1: EPR spectra detected from a chlorobenzene - neutral water-ozone system under uv light irradiation (top) and in dark (middle). The bottom EPR spectrum is a simulated one using the following parameters: $\mathrm{g}=2.0073$, coupling constant $\mathrm{A}_{\mathrm{N}}=7.2 \mathrm{G}(1 \mathrm{~N})$ and $\mathrm{A}_{\mathrm{rH}}=4.1 \mathrm{G}(2 \mathrm{H})$. The top equation
illustrates the reaction of a spin trapping reagent, DMPO (5,5-Dimethyl-1-pyrroline N -oxide), with hydroxyl radical, followed by ozone oxidation of the DMPO-OH adduct to become stable DMPOX radical, which is corresponding to the observed EPR signal.

## Spectroscopic Data:

bis (4-chlorophenyl) methanone (5a)

White solid; ${ }^{1} \mathbf{H} \mathbf{N M R}\left(600 \mathrm{MHz}, \mathrm{CDCl}_{3}\right): \boldsymbol{\delta} 7.69(\mathrm{~d}, J=8.50 \mathrm{~Hz}, 2 \mathrm{H}), 7.43(\mathrm{~d}, J=8.34 \mathrm{~Hz}, 2 \mathrm{H}) .{ }^{13} \mathbf{C}$ NMR ( $150 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ): $\delta 194.0,139.0,135.4,131.2$, and 128.7 .
