S1 Experimental

S1.1 Chemicals and Reagents

Dopamine hydrochloride, Serotonin hydrochloride, and Sodium molybdate were purchased from Sigma Aldrich (99.0% purity). Copper acetate (99.8%) pure was purchased from Merck. Graphite powder (99.8%), Orthophosphoric acid (H₃PO₄, 85%), Thiourea, Potassium dihydro phosphate, Potassium hydrogen phosphate, Potassium permanganate, Sulphuric acid, Hydrogen peroxide, and Sodium Hydroxide used were analytical grade. DW was used in all the experiments.

S1.2 Preparation.

The schematic reactions for the synthesize of $MoS_2/SG/Cu$ nanocomposite are given in *Scheme S1* as follows:

Scheme S1: Scheme representing the synthesis of MoS₂/SG/Cu nanocomposite

S1.3 Instrumentation and Apparatus

X-ray diffraction (XRD) patterns were obtained using the Bruker D8 Discover with Cu-K α radiation (($\lambda = 1.54056$ Å) with a 2 θ range of 10 ° to 80 °. The Raman spectra were obtained on a Dongwoo Optron (Model: Vector-01FX) confocal Raman spectrometer using an argon-ion (488 nm) laser source. Scanning electron microscopy (SEM) was performed using a JEOL (JSM- 7000F) instrument equipped with energy-dispersive X-ray spectroscopy (EDAX) for morphological characterization and semi-quantitative information from the sample surface at a step size of 0.01 ° for the crystal structure analysis. Transmission electron microscope (TEM) observations were carried out using a JEOL 200 kV transmission electron microscope. X-ray photoelectron spectroscopy (XPS) analysis was carried out on a PHI 5000 Versa Probe III X-ray photoelectron spectrometer. The electrochemical activities of the modified electrodes were studied by Cyclic Voltammetry (CV), Chronoamperometry, EIS in a three-electrode system with a platinum wire, Ag/AgCl and a modified GCE as the auxiliary, reference, and the working electrode respectively. All the electrochemical experiments were performed in 0.1 M Phosphate Buffer Solution (PBS).

S1.4 Electrode preparation

For each experiment, the GCE (Glassy carbon electrode) (working electrode) surface was polished in Al₂O₃ slurries (1 μ M and 0.05 μ M) followed by repetitive ultrasonic washing with DIW-EtOH mixture until a mirror-clean surface was obtained. The working electrode was fabricated by drop-casting MoS₂/SG/Cu nanocomposite over the polished GCE. The nanocomposite was dispersed in a 2:1 isopropanol: Nafion mixture under ultrasonication till a uniform texture was achieved, where Nafion acts as the binder. A similar procedure was repeated to fabricate SG/MoS₂ modified GCE. The electrodes obtained were dried at R.T. and used for further electrochemical sensing.
