Experimental Section:

Except where otherwise noted, all substances were commercially available and used in their natural state. Hexane, methanol, and ethyl acetate were obtained from commercial sources and used as reagent-grade solvents. Standard procedures were used to clean and degas the solvents. CDCl_3 was used as the solvent for ^1H NMR and ^{13}C $\{^1\text{H}\}$ NMR measurements on Bruker 400 MHz and 500 MHz spectrometers. Coupling constants (J) are expressed in Hz, and chemical shifts (δ) are expressed in ppm relative to TMS. Chemical shifts and solvent signals (CDCl_3 , δC 77.0 ppm, δH 7.26 ppm) that were used as references were converted to the TMS scale. Commercial aluminium sheets pre-coated with silica gel were used to monitor all of the reactions using analytical thin layer chromatography (TLC). Silica gel (200-400 mesh, Merck) was used for column chromatography. The abbreviations used for ^1H NMR spectra to indicate the signal multiplicity are singlet (s), doublet (d), triplet (t), quartet (q), doublet of doublet (dd), doublet of triplet (dt), triplet of triplet (tt), multiplet (m), etc. The crystal data collection and refinement parameters are outlined in Tables 1 and 2. X-ray diffraction data were obtained using a Bruker P4 diffractometer outfitted with a SMART CCD detector. The structures were resolved by full-matrix least-squares procedures on FP 2 P with SHELXTL after being initially solved by direct methods and conventional difference map techniques (Version 6.10). P30P. On a Rigaku Hg 724+ diffractometer, X-ray diffraction data for binuclear cobalt(II) complexes (**1–3**) were gathered. By visiting www.ccdc.cam.ac.uk/data_request/cif, you can obtain these data from the Cambridge Crystallographic Data Center for free.

The FT-IR data for binuclear cobalt(II) complexes were captured using a Perkin-Elmer FT-IR 2000 spectrometer using KBr discs with a wavelength range of 4000–400 cm^{-1} . The electronic spectra were captured using a Perkin Elmer Lambda 950 UV/VIS Spectrometer in

Dichloromethane (CH₂Cl₂) solvent. Micromass Q-Tof and Bruker Maxis Impact Spectrometers were used for the mass spectrometry measurements. An electrochemistry system made by PAR called the model 273A was used to measure cyclic voltammetry. Three electrodes a working platinum disc (2 mm), auxiliary electrodes, and a saturated Calomel Electrode (SCE) were used. Thermo Finnigan FLASH EA 1112 SERIES (CHNS) Elemental Analyzer was used to perform the elemental analysis. A Quantum Design MPMS XL-5 SQUID magnetometer was used to perform variable temperature susceptibility measurements on ground polycrystalline samples of binuclear cobalt(II) complexes **1** and **2** in the temperature range 5-300 K with an applied magnetic field of 0.1 Ton. Using tables of Pascal's constants, the susceptibility data were adjusted for the sample holders previously measured under the same circumstances and for the contributions of the sample's diamagnetic field.

1. Experimental Procedures and Characterizations
