## S1. Experiment and characterization methods

ZnSO<sub>4</sub>·7H<sub>2</sub>O and LiNO<sub>3</sub> were dissolved in 50 mL of distilled water with different stoichiometric ratio. The solution was kept on a magnetic stirrer and rotated homogeneously to form mixture. After that, ammonia was added to precipitate the dissolved metal ions. The obtained suspension was migrated into a Teflon-lined stainless-steel autoclave and heated up to 180 °C for 8 h. After the hydrothermal reaction, the autoclave was cooled to room temperature. Finally, the sediment was acquired and washed with distilled water and ethanol for 5 times, and then dried at 60 °C overnight in vacuum oven. All the synthesized Li<sub>x</sub>-ZnO (x = 0.00, 0.01, 0.05 and 0.10) were indexed as ZnO, ZnO-Li-1, ZnO-Li-5 and ZnO-Li-10.

The structure and morphology of the ZnO and ZnO-Li-5 were characterized by scanning electron microscopy (SEM, Hitachi S-4800). Energy-dispersive spectroscopy (EDS) elemental scans were performed on the same instrument equip with detector (7593-H, Horiba). The particle X-ray diffraction (XRD) measurements were performed on a Rigaku D/MAXRB diffractometer (Philips, X'pert Pro MPD, Netherlands), and the excitation wavelength is Cu K $\alpha$  radiation ( $\lambda = 0.15443$  nm). Transmission electron microscopy (TEM) and corresponding high-resolution images were obtained using a Philips Tecnai 20U-Twin microscope at an acceleration voltage of 200 kV. As for TEM sample preparation, ZnO and ZnO-Li-5 were dispersed in ethanol and then dropped on a copper micro-grid covered by a carbon film. The specimen for TEM was set statically and dried naturally in the air before its characterization. The room-temperature Raman spectra were measured with 532 nm photons from an Ar<sup>+</sup> laser. The laser power used

was < 1.5 mW. The binding energies of ZnO and ZnO-Li-5 particles were acquired by X-ray photoelectron spectroscopy (XPS) on the Thermo ESCALAB 250 with Al K $\alpha$  radiation (1486.8 eV) as the excitation source. Raman spectra were performed on a Raman spectrometer with 532 nm laser radiation. The electron spin states of the samples were observed via electron paramagnetic resonance (EPR) spectroscopy (Bruker EMXplus). The chemical composition of Li<sub>x</sub>-ZnO were identified by Inductively coupled Plasma Emission Spectrometer Avio 200 (Perkinelmer, USA).

## **S2. Electrochemical characterization methods**

Electrochemical performance was evaluated via assembling and testing CR2032 coin cell. ZnO active materials, carbon black and polyvinylidene fluoride (PVDF) were uniformly dissolved in N-methyl-2pyrrolidone (NMP) with a ratio of 8:1:1, then the slurry was pasted on copper foil and dried in oven under 80 °C to obtain working electrode. Lithium foil, polypropylene film (Celgard 2400) as well as a solution containing LiPF<sub>6</sub> (1M) in vinyl carbonate/dimethyl carbonate/diethyl carbonate (1:1:1 vol%) were used as counter electrode, separator and electrolyte, respectively. The active material had an average loading density of about 1.0 mg and a diameter of 12 mm. Lithium metal has been used as counter and reference electrode. Cyclic voltammetry (CV) and electrochemical impedance spectroscopy (EIS) were conducted on CHI660D electrochemical workstation. The galvanostatic charge/discharge curves are recorded on Neware CT-3008 W battery system.

### S3. Results and discussion

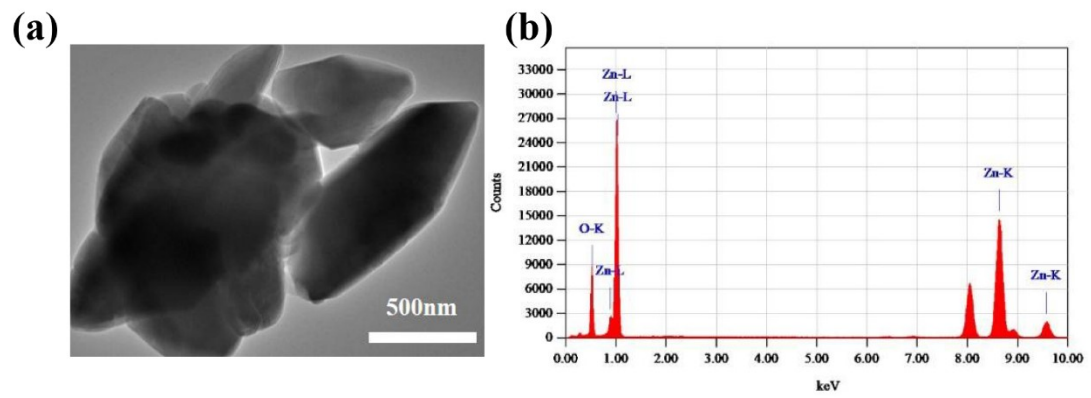

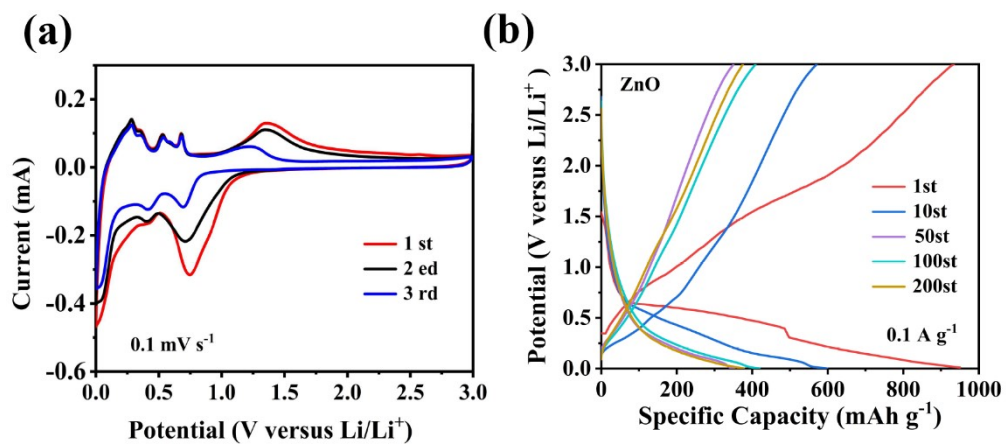

Fig. S1 (a) TEM image and (b) elemental analysis of ZnO nanorod.

**Fig. S2** (a) CV plots at  $0.1 \text{ mV s}^{-1}$  (b) charge/discharge profile of ZnO anode at  $0.1 \text{ A g}^{-1}$ .

$\text{g}^{-1}$ .

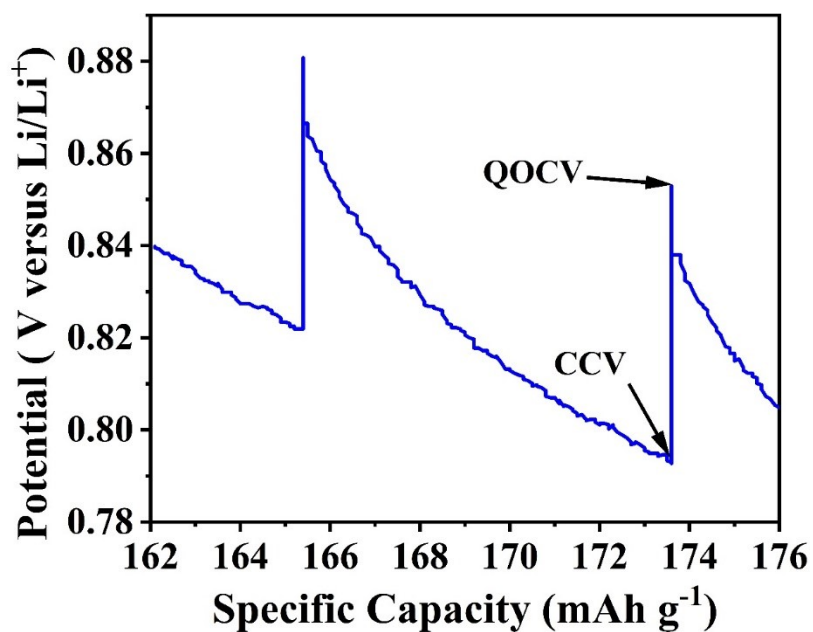

**Fig. S3** Charge/discharge profile of Li-ZnO-1 anode at 0.1 A g<sup>-1</sup>.

**Fig. S4** Charge/discharge profile of Li-ZnO-10 anode at 0.1 A g<sup>-1</sup>.

**Fig. S5** In-situ reaction resistances during charge and discharge processes.

Galvanostatic intermittent titration technique (GITT) was performed to investigate the charge transfer properties and the equilibrium potentials of the ZnO nanorod and Li-ZnO-5 anodes upon cycling. During the GITT measurements, a constant current density of  $0.1 \text{ A g}^{-1}$  for 5 mins was adopted to obtain the closed-circuit voltage (CCV), coupled with duration of 10 mins to collect the quasi-open-circuit voltage (QOCV).
