TGA analysis to calculate  $V_2CT_x$  content in  $VS_4-V_2CT_x$

Assume that the amount lost during thermal decomposition of each component in the  $VS_4-V_2CT_x$  composite sample, and the amount decomposed when the components are pure substances remain constant. At this point we assume that the content of  $V_2CT_x$  and  $VS_4$  in the composite sample is X and Y respectively, thereby setting out the following system of equations:

$$X + Y = 100\%$$

$$X*25.61\% + Y*40.88\% = 37.54\%$$

Therefore, X=21.87% Y=78.13%

The  $Na^+$  ion diffusion ( $D_{Na^+}$ ) for  $VS_4-V_2CT_x$  and  $VS_4$  electrodes is calculated according to the following equation:

$$D_{Na^+} = 0.5(RT/AF^2C\sigma)^2$$

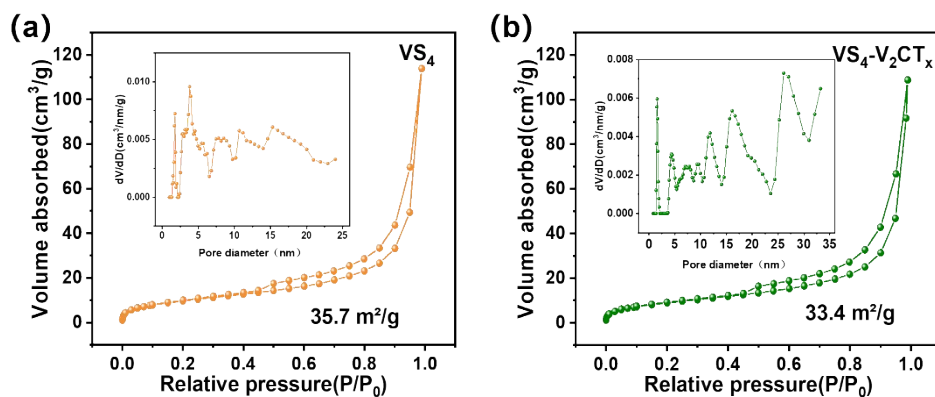

where  $R = 8.314 \text{ J mol}^{-1} \text{ K}^{-1}$ ,  $T = 303.15 \text{ K}$ ,  $A = 1.54 \text{ cm}^2$ ,  $F = 9.6486 \times 10^4 \text{ C mol}^{-1}$ ,  $C \approx 2 \times 10^{-2} \text{ mol cm}^{-3}$ ,  $\sigma$  represents the Warburg impedance coefficient can be obtained from the following equation:

$$Z_{re} = R_e + R_{ct} + \sigma\omega^{-1/2}$$

The  $\sigma_w$  of the two electrodes are obtained by fitting in Figure S6 (b).
