### Note S1. Derivation of random coil lengths of PEG and PDMS chains

In an ideal Gaussian polymer chain, the average end-to-end distance or the random coil length  $d$  is given by:

$$d = b\sqrt{N} \quad (S1)$$

where  $N$  is the number of Kuhn monomers and  $b$  is the Kuhn monomer length.

For polyethylene glycol (PEG), the Kuhn length is  $b_{PEG} = 11 \text{ \AA}$ , and the molar mass of the Kuhn monomer is  $M_0 = 137 \text{ g mol}^{-1}$ .<sup>1</sup> Therefore, for a PEG chain with a molecular weight of 0.6 kDa, there are  $\sim 4.4$  Kuhn monomers, giving a random coil length of 23  $\text{\AA}$ . For a 0.9 kDa PEG chain, there are  $\sim 6.6$  Kuhn monomers, giving a random coil length of 28  $\text{\AA}$ .

For polydimethylsiloxane (PDMS), the Kuhn length is  $b_{PDMS} = 13 \text{ \AA}$ , and the molar mass of the Kuhn monomer is  $M_0 = 381 \text{ g mol}^{-1}$ .<sup>1</sup> Thus, for a PDMS chain with a molecular weight of 3 kDa, there are  $\sim 7.9$  Kuhn monomers, giving a random coil length of 36  $\text{\AA}$ .

## Note S2. Derivation of effective length ratio from ionic conductivity data

Here we map the ionic conductivity observed in the periodic and random DBCPs ( $\sigma_{tot}$ ) to ion diffusion through two 1D slabs in series of PEG with length  $d_{PEG}$ , and of PDMS with length  $d_{PDMS}$ , where the ionic conductivities in each slab is given by  $\sigma_{PEG}$  and  $\sigma_{PDMS}$ , for the PEG and PDMS slabs, respectively. Then the total resistance is given by:

$$R_{tot} = R_{PEG} + R_{PDMS} \quad (S2)$$

$$\frac{d_{tot}}{\sigma_{tot}A} = \frac{d_{PEG}}{\sigma_{PEG}A} + \frac{d_{PDMS}}{\sigma_{PDMS}A} \quad (S3)$$

We note that the resistance is summed in series since the ion travels through the PEG domain and then the PDMS domain of the theoretical 1D slab. We define  $x$  as the length of the PDMS slab relative to the total length of both slides, given by  $x = \frac{d_{PDMS}}{d_{tot}}$ , so that  $1 - x = \frac{d_{PEG}}{d_{tot}}$ . Then we can write:

$$\frac{1}{\sigma_{tot}} = \frac{1-x}{\sigma_{PEG}} + \frac{x}{\sigma_{PDMS}} \quad (S4)$$

Solving for  $x$  we obtain:

$$x = \frac{\sigma_{tot}^{-1} - \sigma_{PEG}^{-1}}{\sigma_{PDMS}^{-1} - \sigma_{PEG}^{-1}} \quad (S5)$$

Finally, we define  $y$  as the ratio of PDMS length to PEG length, given by:

$$y = \frac{d_{PDMS}}{d_{PEG}} = \frac{x}{1-x} = \frac{\sigma_{tot}^{-1} - \sigma_{PEG}^{-1}}{\sigma_{PDMS}^{-1} - \sigma_{tot}^{-1}} \quad (S6)$$

We note that the interpretation of  $y$  is the effective length ratio of slabs of PDMS and PEG that result in identical bulk conductivity ( $\sigma_{tot}$ ) to that measured in the random and periodic DBCPs.

### Note S3. Derivation of aspect ratio from a constant shell thickness

Consider a rectangular channel of PEG with width and thickness given by  $w_{PEG}$  and length  $l_{PEG}$  surrounded by a PDMS shell of uniform thickness  $d$ . Then the total volume, volume of PEG and volume of PDMS are given by:

$$V_{tot} = (l_{PEG} + 2d)(w_{PEG} + 2d)^2 \quad (S7)$$

$$V_{PEG} = l_{PEG}w_{PEG}^2 \quad (S8)$$

$$V_{PDMS} = V_{tot} - V_{PEG} \quad (S9)$$

Solving for the volume fraction of PEG, we obtain:

$$\frac{1}{\phi_{PEG}} = \frac{V_{tot}}{V_{PEG}} = 1 + 4\frac{d}{w_{PEG}} + 4\frac{d^2}{w_{PEG}^2} + 2\frac{d}{l_{PEG}} + 8\frac{d^2}{w_{PEG}l_{PEG}} + 8\frac{d^3}{w_{PEG}^2l_{PEG}} \quad (S11)$$

Let  $a$  be the aspect ratio of PEG defined by,  $a = \frac{l_{PEG}}{w_{PEG}}$ . Let  $y$  be the length of PDMS relative to the length of PEG along the channel length given by  $y = \frac{2d}{l_{PEG}}$ . Then by substituting and factoring, we can write:

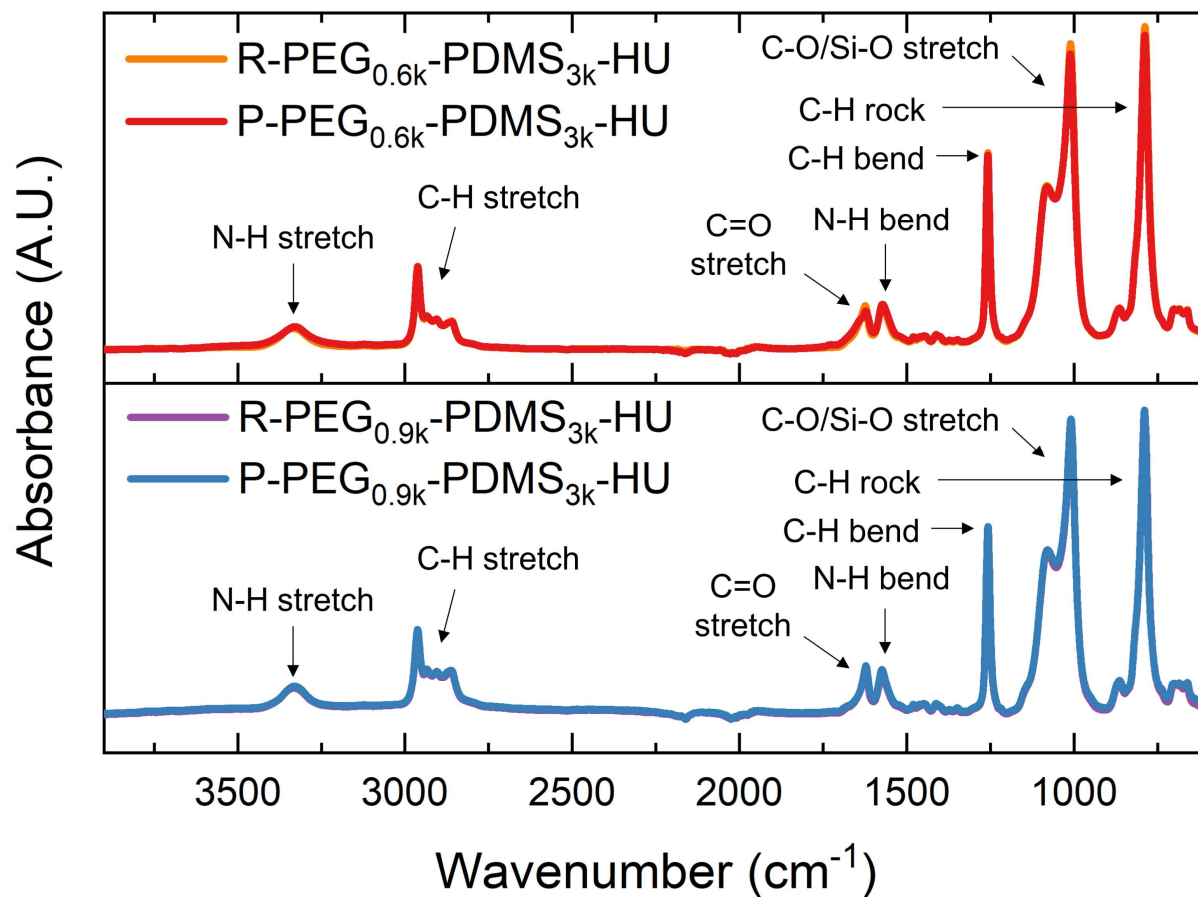

$$\frac{1}{\phi_{PEG}} = (ay + 1)^2(y + 1) \quad (S12)$$

Finally, solving for the aspect ratio we obtain:

$$a = \frac{1}{y} \left[ \left( \frac{1}{\phi_{PEG}(y+1)} \right)^{1/2} - 1 \right] \quad (S13)$$
