## Contents

1. Synthesis ..... S2
2. Representative NMR spectra ..... S7
3. Phase characterization by optical microscopy and DSC ..... S12
4. SAXS data ..... S14
5. Impedance analysis for $\mathrm{A}_{12 \mathrm{~F}}^{23}$ ..... S21
6. UV-induced amorphization ..... S23
7. Overview of phases in polycatenar molecules ..... S24

## 1. Synthesis:

Compounds 3, 5 and $\mathbf{6}$ were synthesized using the procedures reported in ref. [S1], while 3,4,5tris(hexadecyloxy)benzoic acid (7) and the azobenzene-based benzoic acid derivatives were synthesized according to the procedure reported in [S2] and [S3], respectively. The synthesis of other intermediates and of the final polycatenar materials is described below.

## 4-(5-(4-(benzyloxy)phenyl)-1,3,4-oxadiazol-2-yl)phenyl-3,4,5-tris(hexadecyloxy)benzoate (8).

3,4,5-Tris(hexadecyloxy)benzoic acid $7[\mathrm{~S} 2](2.0 \mathrm{~g}, 2.37 \mathrm{mmol}, 1.0$ equiv.) was heated under reflux with excess thionyl chloride ( 3.0 mL ) and a catalytic amount of $\mathrm{N}, \mathrm{N}$-dimethylformamide (DMF) for one hour. The excess of thionyl chloride was removed by distillation under reduced pressure. The acid chloride was then dissolved in dry dichloromethane (DCM, 50 mL ). To this solution, 5-(4-benzyloxyphenyl)-2-(4-hydroxyphenyl)-1,3,4-oxadiazole 6 ( $0.81 \mathrm{~g}, 2.37 \mathrm{mmol}, 1.0$ equiv.) previously dissolved in DCM ( 20 mL ) was added, followed by addition of triethylamine ( 0.29 g $(0.4 \mathrm{~mL})$, TEA, $2.85 \mathrm{mmol}, 1.2$ equiv.) and a catalytic amount of pyridine. The solution was then refluxed for 4 hours under an argon atmosphere. After cooling the reaction mixture to the room temperature, it was washed with $10 \% \mathrm{HCl}(2 \times 50 \mathrm{~mL})$ and several times with cold water, then extracted with DCM $(3 \times 50 \mathrm{~mL})$ and finally dried over anhydrous sodium sulfate. The crude residue obtained after removal of solvent was chromatographed on silica gel using hexane/ethylacetate ( $5: 1$ ) to give the pure compound 8.
8. Colorless solid; m.p. $=83-84^{\circ} \mathrm{C}, 2.04 \mathrm{~g}(1.74 \mathrm{mmol}, 74 \%), \mathrm{C}_{76} \mathrm{H}_{116} \mathrm{~N}_{2} \mathrm{O}_{7} ; M=1169.74 \mathrm{~g} / \mathrm{mol}$; ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 8.20(\mathrm{~d}, J=8.8 \mathrm{~Hz}, 2 \mathrm{H}, \mathrm{Ar}-\mathrm{H}), 8.09(\mathrm{~d}, J=8.8 \mathrm{~Hz}, 2 \mathrm{H}, \mathrm{Ar}-\mathrm{H})$, 7.46-7.35 (m, 5H, Ar-H), 7.41 (s, 2H, Ar-H), 7.38 (d, $J=8.8 \mathrm{~Hz}, 2 \mathrm{H}, \operatorname{Ar}-\mathrm{H}), 7.12$ (d, $J=8.8 \mathrm{~Hz}$, $2 \mathrm{H}, \mathrm{Ar}-\mathrm{H}), 5.16\left(\mathrm{~s}, 2 \mathrm{H}, \mathrm{OCH}_{2}\right), 4.09-4.04\left(\mathrm{~m}, 6 \mathrm{H},-\mathrm{OCH}_{2} \mathrm{CH}_{2}\right), 1.87-1.75\left(\mathrm{~m}, 6 \mathrm{H},-\mathrm{OCH}_{2} \mathrm{CH}_{2}\right)$, 1.59-1.26 (m, 78H, CH2 $), 0.89-0.86\left(\mathrm{~m}, 9 \mathrm{H}, \mathrm{CH}_{3}\right) ;{ }^{13} \mathrm{C}$ NMR ( $101 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta=164.55$, $161.57,153.58,153.01,143.34,136.16,128.77,128.69,128.23,127.48,123.31,122.66,121.65$, $116.55,115.42,108.67,73.61,70.21,69.32,31.91,30.34,29.72,29.69,29.66,29.64,29.62,29.55$, $29.38,29.36,29.34,29.29,26.07,26.04,22.67,14.09$. EA: calc.: C $78.04 \%$, H $10.00 \%, \mathrm{~N} 2.39 \%$; found: C 77.95\%, H 9.90\%, N 2.28\%.

## 4-(5-(4-hydroxyphenyl)-1,3,4-oxadiazol-2-yl)phenyl-3,4,5-tris(hexadecyloxy)benzoate (9)

The benzyl protection group was removed by hydrogenating a solution of the intermediate 8 (1.00 $\mathrm{g}, 0.92 \mathrm{mmol})$ in dry tetrahydrofuran $(50 \mathrm{~mL})$ at low pressure in the presence of $\mathrm{Pd}(10 \%$ on activated carbon) until no further hydrogen uptake was detectable (overnight). Removal of the catalyst by filtration through Celite and evaporation of the solvent yielded $0.90 \mathrm{~g}(98 \%)$ of 9 as pale yellow solid. m.p. $=89-91{ }^{\circ} \mathrm{C}, \mathrm{C}_{69} \mathrm{H}_{110} \mathrm{~N}_{2} \mathrm{O}_{7} ; M=1079.62 \mathrm{~g} / \mathrm{mol} ;{ }^{1} \mathrm{H} \mathrm{NMR}\left(500 \mathrm{MHz}, \mathrm{CDCl}_{3}\right)$ $\delta 8.17$ (d, $J=8.5 \mathrm{~Hz}, 2 \mathrm{H}, \mathrm{Ar}-\mathrm{H}), 8.01$ (d, $J=8.5 \mathrm{~Hz}, 2 \mathrm{H}, \mathrm{Ar}-\mathrm{H}), 7.42$ (s, 2H, Ar-H), 7.38 (d, $J=$ $9.0 \mathrm{~Hz}, 2 \mathrm{H}, \mathrm{Ar}-\mathrm{H}), 7.00$ (d, $J=9.0 \mathrm{~Hz}, 2 \mathrm{H}, \mathrm{Ar}-\mathrm{H}), 6.98$ (s, 1H, OH), 4.09- 4.04 (m, 6H, $\mathrm{OCH}_{2} \mathrm{CH}_{2}$ ), 1.86-1.74 (m, 6H, $-\mathrm{OCH}_{2} \mathrm{CH}_{2}$ ), 1.52-1.25 (m, 78H, CH $)$, $0.89-0.86\left(\mathrm{~m}, 9 \mathrm{H}, \mathrm{CH}_{3}\right) ;{ }^{13} \mathrm{C}$ NMR ( $126 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta=164.76,163.48,159.60,153.60,153.03,143.36,135.77,128.95$, $128.26,125.49,123.25,122.72,121.54,116.30,108.70,73.66,69.34,68.55,31.92,31.91,30.34$, 30.31, 29.74, 29.73, 29.70, 29.67, 29.65, 29.63, 29.56, 29.39, 29.36, 29.35, 29.30, 27.81, 26.08, $26.05,22.67,22.16,14.09$. ## Synthesis of final materials An, $\mathbf{A 1 2 F}_{3}$ and $\mathbf{A 1 2 F}_{23}$

General procedure. The appropriate acid $10 \boldsymbol{n}(0.21 \mathrm{mmol}, 1.0$ equiv.) was heated under reflux with excess thionyl chloride $(1.5 \mathrm{~mL})$ and a catalytic amount of DMF for one hour. The excess of thionyl chloride was removed by distillation under reduced pressure. The acid chloride was then dissolved in dry DCM ( 20 mL ). To this solution, 4-(5-(4-hydroxyphenyl)-1,3,4-oxadiazol-2-yl)phenyl-3,4,5-tris(hexadecyloxy)benzoate 9 ( $0.21 \mathrm{mmol}, 1.0$ equiv.) previously dissolved in DCM ( 10 mL ) was added, followed by addition of TEA ( $0.25 \mathrm{mmol}, 1.2$ equiv.) and a catalytic amount of pyridine. The solution was then refluxed for 4 hours under an argon atmosphere. After cooling the reaction mixture to the room temperature, it was washed with $10 \% \mathrm{HCl}(2 \times 20 \mathrm{~mL})$ and several times with cold water, then extracted with DCM $(3 \times 20 \mathrm{~mL})$ and finally dried over anhydrous sodium sulfate. The crude residue obtained after removal of solvent was chromatographed on silica gel using $\mathrm{CHCl}_{3}$ /ethylacetate (4:1) as eluent. The orange material obtained after removing the solvent was recrystallized from a 1:3 chloroform:ethanol mixture to give the final materials. The analytical data are as follows:

## 4-(5-(4-((4-((4-(Octyloxy)phenyl)diazenyl)benzoyl)oxy)phenyl)-1,3,4-oxadiazol-2-yl)phenyl-

## 3,4,5-tris(hexadecyloxy)benzoate

## 3. Phase characterization by optical microscopy and DSC

Figure S9. Cross-polarized optical micrographs observed on cooling in: a) Col $_{\text {hex }}$ phase of compound $\mathbf{A 8}$ at $111^{\circ} \mathrm{C}$; b) the achiral $\mathrm{Cub}_{\text {bi }} / I a^{3} d$ phase of A8 at $108^{\circ} \mathrm{C}$; c) $\mathrm{Col}_{\text {hex }}$ phase of A10 at $135^{\circ} \mathrm{C}$; d) $\mathrm{Col}_{\text {hex }}$ phase of A16 at $130^{\circ} \mathrm{C}$; e,f) chiral crystalline phase of $\mathbf{A 1 2 F} \mathbf{F}_{23}$ after $15{ }^{\circ}$ rotation one of the analyzers clockwise (e) or anticlockwise (f). The scale bar for all images is given in b).

Figure S10. DSC heating and cooling traces at a rate of $10 \mathrm{~K} \mathrm{~min}^{-1}$ for compounds: a) A8 and b) A12.

## 4. SAXS data

Figure S11. Histograms of electron density for the a) $\mathrm{Cub}_{\mathrm{bi}} / I a^{3} d$ and b) $\mathrm{Cub}_{\mathrm{b} i} / I 23$ phases of $\mathbf{A 8}$.

Figure S12. a) SAXS pattern of $\mathbf{A 8}$ with three phases, recorded upon heating at $102{ }^{\circ} \mathrm{C}$. The (211) peak of $\mathrm{Cub}_{\mathrm{bi}} / I a^{\overline{3}} d$ phase is marked by red color, $\mathrm{Cub}_{\mathrm{b} i} / 23$ indexes are black, and the crystalline peak is labelled as Cr ; b) The hexagonal columnar phase of A8 at $115^{\circ} \mathrm{C}$ upon cooling.

Figure S13. SAXS diffractogram of the Col hexagonal p6mm phase with indexation at $110^{\circ} \mathrm{C}$ upon heating and b) electron density map; high electron density is in purple and low electron density is in red. Lattice is in white. Panel c) shows a room-temperature second-harmonic generation spectrum recorded from $\mathbf{A 1 2 F}_{23}$.

Figure S14. The $n$ dependence of the number of molecules per raft $n_{\text {raft }}$ for hexagonal columnar phase of An at 110 ${ }^{\circ} \mathrm{C}$ except for $\mathbf{A 8}$, which is at $115^{\circ} \mathrm{C}$.

Table S1 Experimental and calculated $d$-spacings, relative integrated intensities, and phases used in the reconstruction of electron densities for the $I a \overline{3} d$ cubic phase of $\mathbf{A 8}$ at $114^{\circ} \mathrm{C}$ upon heating. All intensities are Lorentz and multiplicity corrected.

| $(h k l)$ | $d_{\text {obs. }}(\mathrm{nm})$ | $d_{\text {cal. }}(\mathrm{nm})$ | intensity | phase |

## 5. Impedance analysis for $\mathrm{Al}_{2} \mathrm{~F}_{23}$

Figure S15. Impedance plots for $\mathbf{A 1 2 F}_{23}$ in a $4 \mu \mathrm{~m}$ cell at $118^{\circ} \mathrm{C}$ before and after poling at $5 \mathrm{~V} / \mu \mathrm{m}$. Dashed lines show fitting curves. Comparison with the empty cell yields the following dielectric constants: $\varepsilon=4$ (crystal, 0.1 MHz ), $\varepsilon=7$ (LC), $\varepsilon=10$ (poled LC).

Impedance data were fitted with the following general formula:
$Z=\frac{R_{\text {in }}-j \cdot 2 \pi f C_{i n} R_{\text {in }}^{2}}{1+\left(2 \pi f R_{i n} C_{i n}\right)^{2}}+\frac{R_{b}-j \cdot 2 \pi f C_{b} R_{b}^{2}}{1+\left(2 \pi f R_{b} C_{b}\right)^{2}}+\frac{A_{1}}{(j f)^{\alpha}}$

Here the first term describes an RC circuit resulting from thin interfacial layers between the LC and the contacts, the second term is the bulk RC circuit, and the last term is a constant-phase element. The exponent $\alpha$ is usually close to 1 , and hence the last term becomes $j A_{2} / f$, where $f$ is frequency. The constant-phase element vanishes at high frequencies, not just because of its $1 / f$ behavior, but because the constant $A_{2}$ must be small to fit the low-f part.

For non-zero constants, equation 1 has the following frequency behavior:
$\operatorname{Re}(\mathrm{Z})=\mathrm{Z}^{\prime}: R_{\text {in }}+R_{b}$ at low $f$ and $1 / f \mathrm{C}$ at $\operatorname{high} f$.
$\operatorname{Im}(Z)=Z ": A_{2} / f$ at low $f$ and $1 / f \mathrm{C}$ at high $f$.
However, for $C_{\text {in }} \sim 0, \mathrm{Z}$ ' at high $f$ behaves not as $1 / f \mathrm{C}$, but saturates at the value $R_{\text {in }}$.

## Fit parameters:

before poling: $\mathrm{R}_{\mathrm{in}}=2.30 \pm 0.05 \mathrm{k} \Omega, \mathrm{R}_{\mathrm{b}}=105 \pm 3 \mathrm{k} \Omega, \mathrm{C}_{\mathrm{b}}=245 \pm 6 \mathrm{pF}, \alpha=0.96$
after poling: $\mathrm{R}_{\mathrm{in}}=2.30 \pm 0.05 \mathrm{k} \Omega, \mathrm{R}_{\mathrm{b}}=110 \pm 3 \mathrm{k} \Omega, \mathrm{C}_{\mathrm{b}}=350 \pm 6 \mathrm{pF}, \alpha=0.94$
empty cell: $\mathrm{C}=35 \mathrm{pF}$
Here, similar to some previous studies, we observe a large capacitance and hence a large dielectric constant in a ferroelectric LC. Such results were rebutted in ref. [S5], where after detailed analysis the authors concluded that the large dielectric constant originates not from the LC, but from the thin interfacial layers between the LC and the electrodes. Such interfacial layers were indeed observed in $\mathbf{A 1 2 F}_{\mathbf{2 3}}$, but eliminated after a few poling/heating cycles. This is seen in Figure S16 that reveals the high-frequency saturation of $Z$ ' after cycling. Hence this study justifies the assignment of large dielectric constant to a ferroelectric LC.

Figure S16. Impedance plots of the same $\mathbf{A 1 2 F}_{23}$ sample before and after elimination of the interfacial capacitance. The elimination is obvious from the different number of semicircles in the Nyquist plot (left), and from the different high-frequency behavior of Z' (right).

## 6. UV-induced amorphization

Figure S17. Left: Room-temperature SAXS patterns from A12 before and after irradiation with 350 nm light. Right: DSC curves from A18 before and after UV irradiation.

The UV-induced amorphization, which was suggested by polarized optical microscopy, was confirmed by SAXS and DSC. For SAXS experiments, we have squeezed a piece of molten material between two pieces of kapton tape, and then separated them by peeling. This resulted in two large-area thin samples ( $\sim 5 \mu \mathrm{~m} \times 2 \mathrm{~mm} \times 5 \mathrm{~mm}$ ), which were almost completely amorphized by a few-second irradiation with 350 nm light $\left(40 \mathrm{~mW} \mathrm{~cm}{ }^{-2}\right)$ in the LC phase, as demonstrated by the SAXS patterns in the left part of Figure S17. The relatively large width of the main LC peak before irradiation is an collimation artefact resulting from the large area of the sample, which was required to accumulate a measurable signal after irradiation; this artefact originates from the finite size of detector, which is illuminated by a slightly divergent X-ray beam.

Due to technical limitations in sample preparation and lower sensitivity of DSC compared to SAXS, DSC measurements were performed on a thicker sample ( $\sim 20 \mu \mathrm{~m}$ ). Hence, a crystallization peak was reduced, but not erased, by the UV illumination with the same parameters. Nevertheless, a glass transition shoulder did appear at $\sim 32{ }^{\circ} \mathrm{C}$, providing an additional confirmation to the UVinduced amorphization.

## 7. Overview of phases in polycatenar molecules

We have derived the overall relationship between molecular length and phases by combining data from our present and previous studies.[S6-S8] With the increase of alkyl volume (represented as total number of carbon atoms), the phase transition sequence is $\mathrm{Sm}-I a^{\overline{3}} d-I 23-\mathrm{Tet}_{\mathrm{bi}}-I a 3 d-$ p6mm.

Table S12 Alkyl chain size and mesophase types of compounds $\mathbf{B m} / \boldsymbol{n}$ and $\mathbf{C m} / \boldsymbol{n}$

| Cpd. | $m$ | $n$ | Carbon atoms in alkyl chains | Phases |
| :---: | :---: | :---: | :---: | :---: |
| B | 6 | 4 | 16 | Sm |
|  | 6 | 5 | 17 | Sm |
|  | 6 | 6 | 18 | Sm |
|  | 6 | 7 | 19 | $\mathrm{Sm}-\mathrm{Ia}{ }^{3} d$ |
|  | 6 | 8 | 20 | $\mathrm{Sm}-I a^{3} d$ |
|  | 6 | 9 | 21 | $I a^{3} d$ |
|  | 6 | 10 | 22 | $I a^{3} d$ |
|  | 6 | 12 | 24 | $I a^{3} d$ |
| C | 10 | 5 | 35 | 123 |
|  | 10 | 6 | 36 | 123 |
|  | 10 | 7 | 37 | I23 |
|  | 10 | 8 | 38 | 123 |
|  | 10 | 9 | 39 | 123 |
|  | 10 | 10 | 40 | 123 |
|  | 10 | 12 | 42 | 123 |
|  | 10 | 14 | 44 | $I 23-\mathrm{Tet}_{\mathrm{bi}}-I a^{3} d$ |
|  | 10 | 16 | 46 | $I 23-\mathrm{Tet}_{\mathrm{bi}}-I a^{3} d$ |
|  | 10 | 18 | 48 | $I 23-\mathrm{Tet}_{\mathrm{ij}}-I a^{3} d$ |
|  | 10 | 20 | 50 | $I a^{3} d$ |

Overall, the sequence proceeds from lamellar to columnar phases via 3D networks. This sequence is related to the increase of inter-material dividing surface curvature, i.e. the increasing alkyl volume gradually encloses the molecular rafts of aromatic cores. Interestingly, if we focus on the cubic phases, we can identify a phase sequence of $I a^{\overline{3}} d-I 23-I a^{\overline{3}} d$. The typical twist angles between neighboring rafts are $\sim 7.3^{\circ}$ for $I a^{\overline{3}} d$ of $\mathbf{B} \boldsymbol{m} / \boldsymbol{n}, \sim 7.7^{\circ}$ for $I 23$ and $\sim 8^{\circ}$ for $I a^{\overline{3}} d$ of $\mathbf{C m} / \boldsymbol{n}$. Thus, for polycatenar molecules, the volume of alkyl chains controls the transition from lamellar
to columnar phase. The intermediate cubic phases are controlled by the twist angle of molecular rafts.
