# 1. Experiments

## 1.1 Optimization of synthesis conditions for FPTA NPs

To enhance fluorescence intensity of prepared FPTA NPs, the effect of various experimental conditions was explored. The fluorescence signal was determined by changing the concentration of TA from 0.01 g/mL to 0.05 g/mL, the concentration of NaOH from 0.001 g/mL to 0.005 g/mL, the addition amount of H<sub>2</sub>O<sub>2</sub> from 1 mL to 5 mL and the reflux reaction time from 1 h to 5 h, respectively. As shown in Fig.S1, using 0.03 g/mL of TA, 0.003 g/mL of NaOH and 4 mL of H<sub>2</sub>O<sub>2</sub> and reflux time for 3 h were finally screened out to be the optimized reaction conditions for synthesizing FPTA NPs.

## 1.2 Calculation of quantum yield of FPTA NPs

Quinine sulfate (Qs) was used as the standard reference material to measure the fluorescence quantum yield (QY) of the FPTA NPs. Firstly, a certain amount of Qs was dissolved in 0.1 M H<sub>2</sub>SO<sub>4</sub> solution, and the absorbance A at 350 nm was recorded, by the way, the absorbance was kept below 0.1. Subsequently, the fluorescence emission peak integral area F of the same solution excited at 350 nm was recorded, thus, the linear fitting line between absorbance A as X axis and integral area F as Y axis is obtained, and the slope [ $K_{Qs}$ ] is also obtained. The same experimental method is used to measure the FPTA NPs solution and obtain the slope [ $K_s$ ]. The quantum yield of Qs is reported to be 54 %<sup>1</sup>, according to the following formula to calculate the QY of FPTA NPs.

$$\Phi_s = \Phi_{Qs} \times \frac{\eta_s^2 F_s A_{Qs}}{\eta_{Qs}^2 A_s F_{Qs}} = 54 \% \times \frac{K_s}{K_{Qs}}$$

Where  $\Phi$  is the QY, subscripts S and Qs refer to FPTA NPs and quinine sulfate,  $\eta$  is the refractive index of the solvent, for these aqueous solutions,  $\eta_s/\eta_{Qs}=1$ .

## 1.3 FPTA NPs functionalized filter paper strips for visual detection

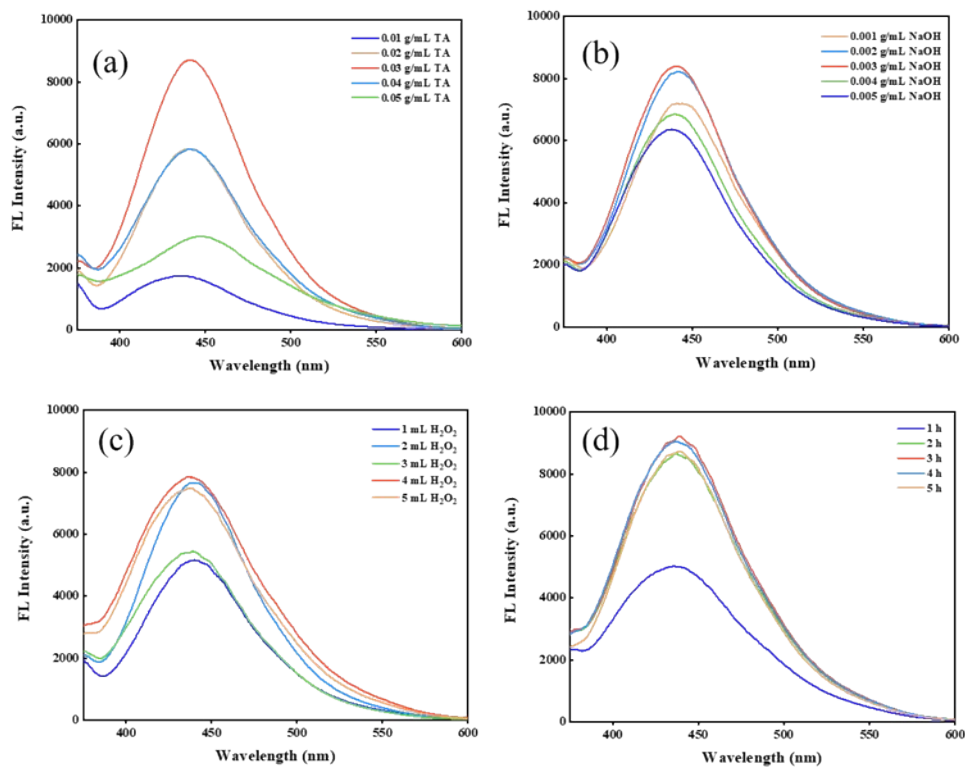

The filter paper was first cut into circular paper strips (each with a diameter of 5 mm), immersed in FPTA NPs solution (1.7 mg/mL) for 10 minutes, and then removed from the FPTA NPs solution and dried in air. The FPTA NPs-functionalized paper

strips were stored in a sealed bag for further use. Various concentrations of  $\text{Bi}^{3+}$  (15  $\mu\text{L}$ ) were dropped onto the FPTA NPs-functionalized paper strips and dried in air, respectively. Photographs of the test paper were taken using a smartphone under both natural light and a 365 nm UV lamp.

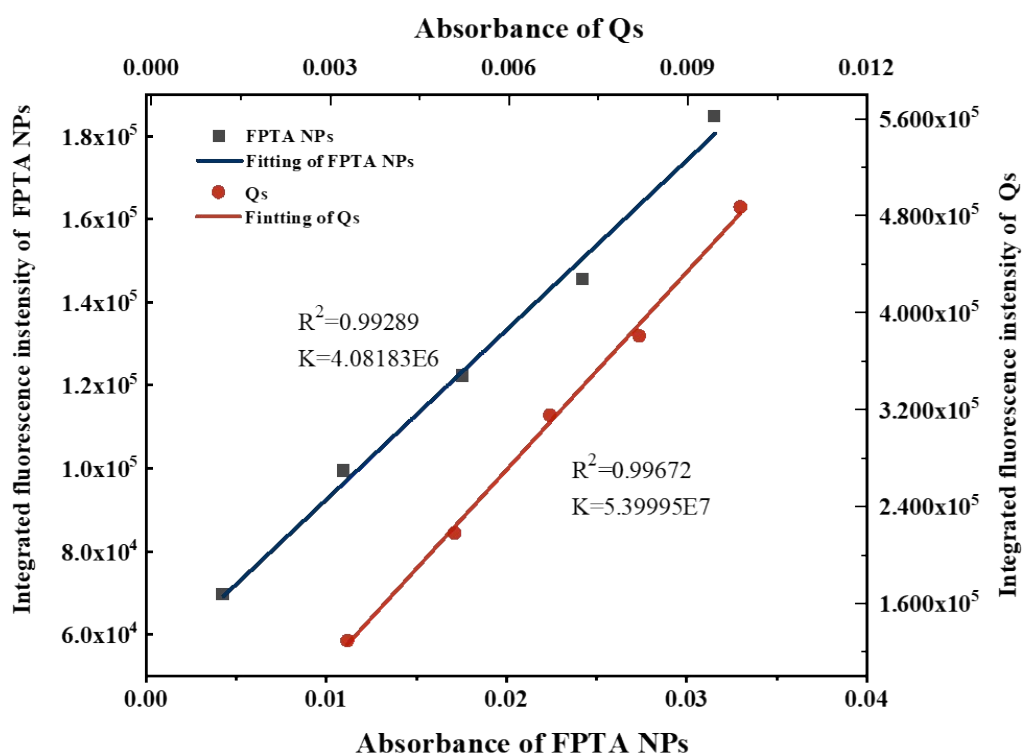

#### **1.4 Spectroscopic titrations**

Based on the photophysical results of FPTA NPs in presence of  $\text{Bi}^{3+}$ , its ability to bind to FPTA NPs was evaluated by spectroscopic titration with  $\text{Bi}^{3+}$  addition. The stoichiometric ratio of FPTA NPs with  $\text{Bi}^{3+}$  was analyzed through a Job's plot. The mixed solutions were prepared with different proportions of  $\text{Bi}^{3+}$  to FPTA NPs, specifically 1:9, 2:8, 3:7, 4:6, 5:5, 6:4, 7:3, 8:2, and 9:1. For each of these proportions, the adsorption intensities of the mixed solutions were measured at 278 nm. These intensities were then plotted against the concentration, expressed as  $(A-A_0)$  versus the ratio of  $[\text{Bi}^{3+}]$  to the total concentration of  $[\text{Bi}^{3+}]+[\text{FPTA NPs}]$ .
