## 1. General methods

Unless otherwise stated, all manipulations were performed using standard Schlenk techniques under dry argon in flame-dried glassware or in a MBraun argon-filled glove box.

Anhydrous solvents were distilled from appropriate drying agents and were transferred under Ar (DCM and *n*-pentane (CaH<sub>2</sub>), CDCl<sub>3</sub> (molecular sieves)) and stored over 4 Å molecular sieves under argon prior to use. Anhydrous BiCl<sub>3</sub> (99.9%, trace metal basis) and NaBAr<sup>F</sup> were purchased from Alfa Aesar, BiPh<sub>3</sub> was purchased from abcr. Trimesitylbismuth and tris(3,5-di-*tert*-butylphenyl)bismuthane have been synthesized by the reported method.<sup>1</sup>

NMR data were recorded using a Bruker AVIII HD 300 MHz, Bruker AVIII HD 400 MHz, Bruker AVIII 500 MHz or Bruker AVNeo 600 MHz NMR spectrometer. Chemical shifts ( $\delta$ ) are given in ppm, relative to deuterated solvent residual peak, and coupling constants ( $J$ ) provided in Hz. <sup>1</sup>H and <sup>13</sup>C chemical shifts  $\delta$  are reported relative to the solvent residual peaks as an internal reference. For <sup>1</sup>H NMR the following residual proton peaks of the deuterated solvents were used: CDCl<sub>3</sub>,  $\delta_{\text{H}} = 7.260$  ppm, CD<sub>2</sub>Cl<sub>2</sub> = 5.320 ppm and for <sup>13</sup>C NMR: CDCl<sub>3</sub>,  $\delta = 77.16$  ppm. <sup>19</sup>F NMR data measured at 585 MHz was generally measured without <sup>1</sup>H decoupling.

## 2. Synthesis of Triarylbi-muth Complex

Trimesitylbismuth and tris(3,5-di-*tert*-butylphenyl)bismuthane have been synthesized by the reported method,<sup>1</sup> while triphenylbismuth was commercially available.

### 2.1 Synthesis and characterization data of tris(3,5-di-methylphenyl)bismuthane (2)

**Procedure:** A flame-dried Schlenk-flask was charged with activated magnesium turnings (214.7 mg, 8.8 mmol, 1.2 equiv.) and dissolved in anhydrous THF (0.5 mL), followed by the addition of iodine and 0.5 mL of 5-bromo-xylene (0.37 mmol). The mixture was gently heated with a heat gun (70 °C) and a solution of the remaining 5-bromo-xylene (0.95 mL, 7 mmol, in total: 1.0 equiv.) in anhydrous THF (15 mL) was slowly added. The mixture was placed in an oil bath and heated at 70 °C for 3 h. Then, the solution was cooled to room temperature, additional 10 mL of anhydrous THF were added. The mixture was cooled to 0 °C and BiCl<sub>3</sub> was added in one portion. The reaction was allowed to warm up to room temperature and stirred overnight. The solvent was evaporated under reduced pressure and the crude mixture was extracted with anhydrous *n*-pentane (3× 10 mL). The removal of pentane under vacuum afforded tris(3,5-di-methylphenyl)bismuth (2). **Yield:** 88% (1.02 g)

### 3.5 SC-XRD of triaryldibismuth dichlorides **6**, **7** and **8**

Complexes **5** and **8** are known,<sup>2,3</sup> **6** and **7** represent new structures.

**Figure S1.** Solid state of structure of **6** (A), **7** (B)<sup>4</sup> and **8** (C)<sup>4</sup>. Ellipsoids are drawn at the 50% probability level. H atoms are omitted for clarity. Selected bond lengths (Å) and angles (°): (A) **6**, Bi1–C1: 2.1980(15), Bi1–C9: 2.202(2), Bi1–C11: 2.5898(4), C11–Bi1–C11, 177.391(18). (B) **7**, Bi1–C1: 2.221(2), Bi1–C15: 2.212(3), Bi1–C11, 2.5954(5), C11–Bi1–C11, 178.59(3). Selected bond lengths (Å) and angles (°) are the average of two molecules in the asymmetric unit cell: (C), **8**: Bi1–C1:2.239(3), Bi1–C19: 2.2315(3), Bi1–C10: 2.235(3), Bi1–C11: 2.5977(8), Bi1–C12: 2.63265(8), C11–Bi1–C12: 175.94(3).

Structures **6**, **7** and **8** adopt a slightly distorted trigonal bipyramidal geometry with the chloride atoms occupying the apical positions. The Bi1–C11 bond lengths of **6**, **7** and **8** are in the range of the unsubstituted  $\text{Ph}_3\text{BiCl}_2$  [**5**: 2.5896(10) Å;<sup>2</sup> **6**: 2.5898(4); **7**: Bi1–C11 = 2.5954(5) Å; **8**: 2.6151(8) Å;]. Whereas the fluorinated analogues  $^t\text{BuAr}_3\text{BiF}_2$  ( $^t\text{BuAr}$  = 3,5-*t*Bu<sub>2</sub>-C<sub>6</sub>H<sub>3</sub>) and  $\text{Mes}_3\text{BiF}_2$  (Mes = 2,4,6-Me<sub>3</sub>-C<sub>6</sub>H<sub>3</sub>) display a quasi-linear F–Bi–F axis [ $^t\text{BuAr}_3\text{BiF}_2$ : 179.1(2)°;  $\text{Mes}_3\text{BiF}_2$ : 179.00(5)°],<sup>1</sup> complexes **6**, **7** and **8** exhibit deviations from linearity with Cl–Bi–Cl angles of 177.391(18)° (**6**), 178.59(3)° (**7**) and 175.94(3)° (**8**). The replacement of the more electronegative fluoride ligands with chlorine atoms leads to a distinct organization of the aryl groups, adopting rather a propeller-like configuration in all cases.

This effect can be attributed to the weaker interactions of the *ortho* C–H bonds with the Cl as a result of the lower electronegativity compared to fluorine.

## 5. Reactivity of Chlorotrimesitylbismuthonium salt (**13**)

**Procedure:** In the glovebox, an oven dried vial with a septum cap was charged with the corresponding chlorotrimesitylbismuthonium salt (**12**) (50 mg, 0.03 mmol, 1.0 equiv.) and pyridine-N-oxide (3.4 mg, 0.04 mmol, 1.05 equiv.), followed by the addition of 5 mL of anhydrous dichloromethane. The reaction was stirred for 2 h at room temperature, and afterwards the solvent was evaporated under reduced pressure using the Schlenk line, affording a light yellowish solid. **Yield:** 87.7 % (46.7 mg)

$^1\text{H NMR}$  (600 MHz,  $\text{CDCl}_3$ )  $\delta$  7.98 (d,  $J = 6.1$  Hz, 2H,  $H-7$ ), 7.72 – 7.66 (m, 8H,  $\text{BAr}^{\text{F}}$ ), 7.52 (t,  $J = 7.7$  Hz, 1H,  $H-9$ ), 7.50 (s, 4H,  $\text{BAr}^{\text{F}}$ ), 7.38 – 7.31 (m, 2H,  $H-8$ ), 7.22 (s, 6H,  $H-3$ ), 2.55 (s, 18H,  $H-5$ ), 2.33 (s, 9H,  $H-6$ ).

$^{13}\text{C NMR}$  (151 MHz,  $\text{CDCl}_3$ )  $\delta$  163.3 (C-1), 161.8 (q,  $J = 49.9$  Hz,  $\text{BAr}^{\text{F}}$ ), 143.4 (C-4), 142.0 (C-2), 139.0 (C-7), 134.9 (m) ( $\text{BAr}^{\text{F}}$ ), 133.1 (C-3), 132.8 (bs) (C-9), 129.1 (qq,  $J = 31.5, 2.8$  Hz,  $\text{BAr}^{\text{F}}$ ), 127.3 (C-8), 124.6 (q,  $J = 272.7$  Hz,  $\text{BAr}^{\text{F}}$ ), 117.6 (hept,  $J = 4.0$  Hz,  $\text{BAr}^{\text{F}}$ ), 25.0 (C-5), 21.0 (C-6).

$^{19}\text{F NMR}$  (565 MHz,  $\text{CDCl}_3$ )  $\delta$  -62.5.

The connectivity of the pyridine-N-oxide with the Bi-species is supported based on a NOESY cross peak between  $H-5$  and  $H-7$ . The carbon signal of C-9 is surprisingly broad. The observed  $^{15}\text{N NMR}$  shift (-108.0 ppm) is lower compared to the value of the free oxide (-87.5 ppm, DMSO), but higher compared to the pyr-NO\* $\text{TFA}$  (-135.7 ppm).<sup>5</sup> As also the MS department could not find the mass of the cationic species, the binding of the N-oxide might be weak and might also explain the observations from the NMR data.

**HRMS:** MS department could not find the mass of the cationic species (**13**), but rather compound **12**.

**SC-XRD:** Crystal of sufficient quality for SC-XRD was obtained *via* liquid-liquid diffusion of pentane into a concentrated solution of complex **13** in  $\text{CH}_2\text{Cl}_2$  at  $-18$  °C

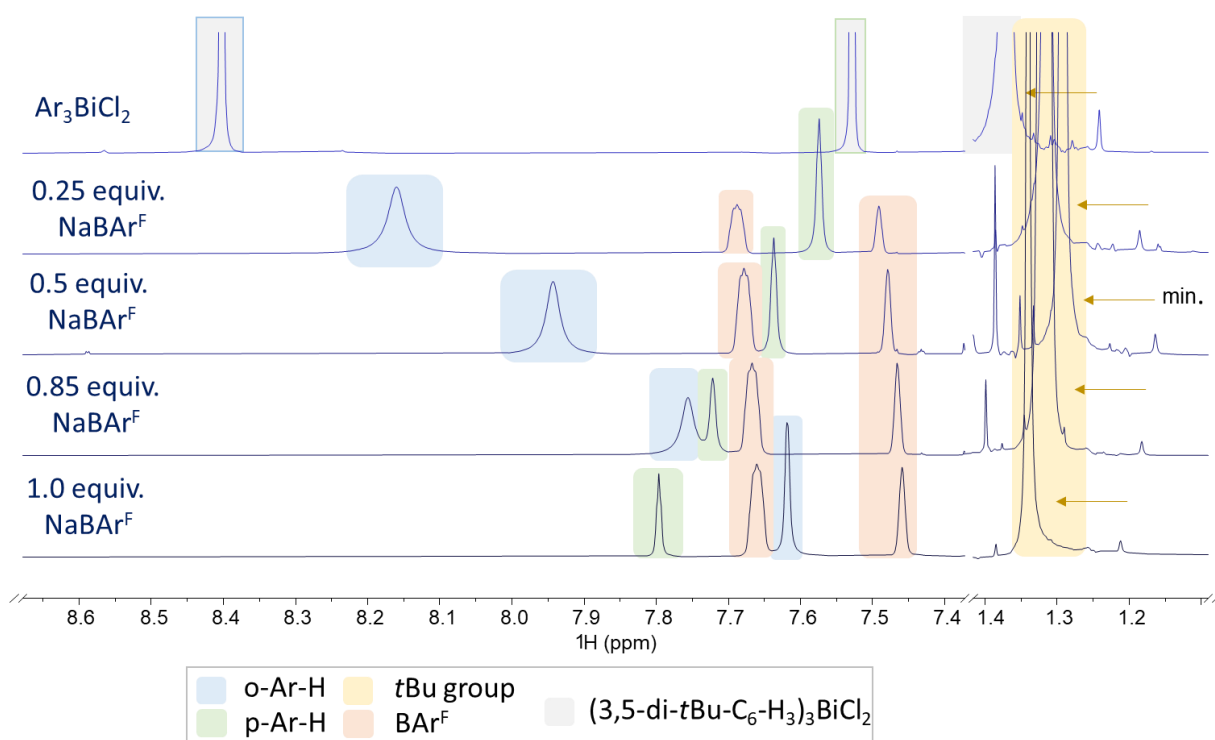

## 6. DOSY Experiments

After we observed that the addition of 1.0 equiv. of NaBAR<sup>F</sup> to complex **7** resulted in the formation of a formally monomeric chlorobismuthonium salt **11** in solution and a dimeric bismuthonium salt **11a** in solid-state, we repeated the reaction with 0.5 equiv. of NaBAR<sup>F</sup> (Scheme S2). This reaction led to the formation of a dimeric chlorobismuthonium salt **11a** in solution and solid state. However, the <sup>1</sup>H NMR spectrum of this reaction displays broader signals in comparison to the addition of 1.0 equiv. of NaBAR<sup>F</sup> (Figure S2.), indicating a fast dynamic exchange between different species in solution.

**Scheme S2.** Synthesis and crystallization of chlorotriaryl bismuthonium salts **11** and **11a**.

In contrast to the reaction of **6** with 0.5 equiv. of NaBAR<sup>F</sup> where compound **6** crystallized, the installation of <sup>t</sup>Bu-substituents in *meta*-position might facilitate the formation of the dimeric structure *via* London dispersion forces.<sup>6-8</sup> In order to understand the dynamic behaviour of this chlorobismuthonium species **11** and **11a**, we carried out this reaction with different amounts of NaBAR<sup>F</sup> (1.0, 0.85, 0.5 and 0.25 equiv.). As depicted in Figure 2, a trend can be clearly observed: as the amounts of NaBAR<sup>F</sup> decrease, the signals of the observed bismuth species are more similar to **6**, however, separate Bi species were not observed at any time in the <sup>1</sup>H NMR spectra.

**Figure S2.** Stacked <sup>1</sup>H NMR spectra of the reaction of complex **7** with various amount of  $\text{NaBAR}^{\text{F}}$  (1.0, 0.85, 0.5, 0.25 equiv.) in  $\text{CH}_2\text{Cl}_2$  at 25 °C for 2 h. The precipitate was filtered off and the <sup>1</sup>H NMR spectra were recorded (500 MHz,  $\text{CDCl}_3$ ).

Furthermore, the addition of 1.0 equiv. of  $\text{NaBAR}^{\text{F}}$  leads to sharper signals, whereas a reduced amount of the halide scavenger results in broader signals. Whereas all the aromatic H signals experience a shift with an increased amount of  $\text{NaBAR}^{\text{F}}$ , the chemical shift of the <sup>t</sup>Bu groups reaches a minimum at 0.5 equiv.. This indicates that a fast and reversible equilibrium between at least three different species is present in solution after the abstraction of a chloride from the Bi. These results again, are in stark contrast to the behaviour of the analogous fluorobismuthonium salt.<sup>1</sup>

To gain deeper insights into the distinct behavior of chlorobismuthonium salts in both solution and solid-state, we conducted DOSY (Diffusion Ordered Spectroscopy) experiments. For this, different amount of equivalents of  $\text{NaBAR}^{\text{F}}$  (1.0, 0.85, 0.5, 0.25 equiv.) were added to **7**, and the reaction was left to stir for 2 h at room temperature. After this time, the precipitate was removed through filtration, and subsequent evaporation under Schlenk vacuum conditions yielded the corresponding chlorobismuthonium salts, for which <sup>1</sup>H NMR spectra were recorded (see Figure S2). Based on these, the self-diffusion coefficients  $D_{\text{self}}$  were determined (Figure S3).

Figure S3 illustrates the self-diffusion coefficients. Increased quantities of NaBAr<sup>F</sup> result in decreased  $D_{\text{self}}$  values, suggesting the formation of molecules with higher molecular masses, potentially as dimeric species. However, it cannot be ruled out that the presence of BAr<sup>F</sup> as anion might distort the values in the solution.

**Figure S3.**  $D_{\text{self}}$  values of chlorobismuthonium salts after the addition of different equivalents of NaBAr<sup>F</sup>.

## 7. Determination of Lewis acidity

The Lewis acidity of the chlorotriarylbi-muthonium salts was determined by the Gutmann-Beckett-method. This method is based on the use of triethylphosphine oxide ( $\text{Et}_3\text{P}=\text{O}$ ) as Lewis base which interacts with the Lewis acid, resulting in a chemical shift ( $\delta$ ) of the phosphine oxide in the  $^{31}\text{P}$  NMR spectrum.

The strength of the Lewis acidity is determined by the acceptor number (AN), which is calculated as followed:

$$\text{AN}(\text{Et}_3\text{PO}) = 2.21 \cdot (\delta_{\text{P(LA)}} - 41.0)$$

**Table S1.** Determination of the Lewis acidity by the acceptor number in  $\text{CD}_2\text{Cl}_2$ . Equimolar amounts of the corresponding Lewis acid and Lewis base ( $\text{Et}_3\text{PO}$ ) were dissolved in  $\text{CD}_2\text{Cl}_2$ . The  $^{31}\text{P}$  NMR spectra were recorded at 121.5 MHz at 298 K. Stacked  $^{31}\text{P}$  NMR spectra of the corresponding  $\text{Ar}_3\text{BiCl} \cdot \text{OPEt}_3$  adduct are shown in Figure S8 and S9.

Entry	Compound	$\delta^{31}\text{P}$ (ppm)	AN
1	$\text{Et}_3\text{PO}$	50.45	
Formally monomeric Bi species:			
2	$[\text{Ph}_3\text{BiCl}][\text{BAr}^{\text{F}}]$ ( <b>9</b> )	69.86	63.78
3	$[\text{3,5-Me}_2\text{-C}_6\text{H}_3\text{-BiCl}][\text{BAr}^{\text{F}}]$ ( <b>10</b> )	68.29	60.31
4	$[\text{3,5-}i\text{Bu}_2\text{-C}_6\text{H}_3\text{-BiCl}][\text{BAr}^{\text{F}}]$ ( <b>11</b> )	67.67	58.94
5	$[\text{Mes}_3\text{BiCl}][\text{BAr}^{\text{F}}]$ ( <b>12</b> )	60.85	43.86
Formally dimeric Bi species:			
6	$[(\text{Ph}_3\text{BiCl})_2][\text{BAr}^{\text{F}}]$ ( <b>9a</b> )	69.88	63.82
7	$[((\text{3,5-Me}_2\text{-C}_6\text{H}_3)_3\text{-BiCl})_2][\text{BAr}^{\text{F}}]$ ( <b>10a</b> )	68.30	60.33
8	$[((\text{3,5-}i\text{Bu}_2\text{-C}_6\text{H}_3)_3\text{-BiCl})_2][\text{BAr}^{\text{F}}]$ ( <b>11a</b> )	67.67	58.94

Table S1 displays the  $^{31}\text{P}$  NMR chemical shifts and acceptor numbers of the chlorotriarylbi-muthonium salts (9-12 and 9a-11a). A closer look into the chemical shifts and acceptor numbers of the formally monomeric Bi species indicates a ligand effect on the Lewis acidity. The more steric the aryl-ligand, the lower the AN, resulting in a lower Lewis acidity. The  $^{31}\text{P}$  NMR of complex **9** displays three signals at  $\delta_{\text{P}}=78.65$ ,  $\delta_{\text{P}}=69.86$  and  $\delta_{\text{P}}=55.64$  ppm in  $\text{CD}_2\text{Cl}_2$ .

The experimental observation on the formally dimeric Bi species show the same trend as the formally monomeric. Furthermore, the dimeric species show identical  $^{31}\text{P}$  NMR shifts as the corresponding monomeric structures, indicating the formation of a monomeric  $\text{Ar}_3\text{BiCl} \cdot \text{OPEt}_3$  adduct and  $\text{Ar}_3\text{BiCl}_2$ , which is further confirmed by the  $^1\text{H}$  NMR spectra, emphasizing a dynamic equilibrium in solution (Figure S4).

**Figure S4.** Formation of  $\text{Ar}_3\text{BiCl}\cdot\text{OPEt}_3$  adduct and  $\text{Ar}_3\text{BiCl}_2$  after the addition of  $\text{Et}_3\text{PO}$  to dimeric chlorobismuthonium salts (**9a-11a**).

Complete .cif-data of the compound are available under the CCDC number **CCDC-2356071**.

A resolution cut-off (SHEL 999 0.70) was applied to the data set to exclude the poorly determined reflections at high diffraction angles. The terminal  $-CF_3$  groups show strong rotational disorders over two or more positions. The ISOR instruction was applied to several F atoms in the main part of the  $-CF_3$  rotational disorders. Atomic occupancies have been refined with fixed values and isotropic displacement parameters are applied to atoms in the minor parts of the disorder.

Complete .cif-data of the compound are available under the CCDC number **CCDC-2356070**.

A resolution cut-off (SHEL 999 0.71) was applied to the data set to exclude the poorly determined reflections at high diffraction angles. The terminal  $-\text{CF}_3$  groups show strong rotational disorders over two or more positions. They were partially described using the DSR tool plug-in in Olex2.<sup>9,10</sup> For the minor parts of the disorders isotropic displacement parameters were used and atoms were refined with

fixed occupancy values. The ISOR instruction was applied to several F atoms in the main part of the - CF<sub>3</sub> rotational disorders. In addition, the DFIX instruction was used to fix the C...F distances.
