**Section-1: Materials and experimental section**

Materials: Phenol, resorcinol, and hexamethylenetetramine were purchased from Loba Chemie, India. Trichloroacetic acid, dimethyl acetamide, mesitylene, dioxane, acetic acid, tetrahydrofuran, ethanol, and methanol were purchased from Spectro-chem, India. All these chemicals were used without further purification. The water used in all the experiments was purified through a Millipore system.
Synthesis of 2,4-dihydroxy-1,3,5-triformylcarbaldehyde (DHTA):

This compound was synthesized following the previously reported method.[1] In an oven dried 100 mL round bottom flask, 5.5 g (50 mmol, 1 eq.) of resorcinol and hexamethylenetetramine (110 mmol, 2.2 eq.) was taken followed by addition of 50 mL trichloroacetic acid at 0 ˚C under argon atmosphere. Then, the mixture was heated to 130 ˚C for 16 h followed by heating at 150 ˚C at 3 h. Then 80 mL 3M HCl was added after cooling the solution to 100 ˚C. Then, the solution was again heated to 105 ˚C for another 30 min. After cooling to the room temperature, the solution was filtered followed by extraction with dichloromethane. Then, solution was dried over magnesium sulphate followed by filtration. Rotary induced evaporation led to the formation of off-white powder.

^{1}H NMR (400 MHz, DMSO-d_6) δ 10.25 (s, 1H), 10.08 (s, 2H), 8.38 (s, 1H). ^{13}C NMR (101 MHz, DMSO-d_6) δ 194.37, 190.40, 170.64, 141.09, 116.21, 110.46.
DHTA

DHTA
Synthesis of 2-hydroxy-1,3,5-triformylcarbaldehyde (HTA):

This compound was synthesized following the previously reported method.[2] In an oven dried 100 mL round bottom flask, 1.9 g (20 mmol, 1 eq.) of phenol and hexamethylenetetramine 5.9 g (42 mmol, 2.1 eq.) was taken followed by addition of 50 mL trichloroacetic acid at 0 ˚C under argon atmosphere. Then, the mixture was heated to 120 ˚C for 20 h followed by heating at 150 ˚C at 30 min. Then 50 mL 3 M HCl was added after cooling the solution to 100 ˚C. Then, the solution was again heated to 105 ˚C for another 30 min. After cooling to the room temperature, yellow precipitate was filtered and washed thoroughly with cold ethanol to obtain pale yellow product.

^{1}H NMR (400 MHz, DMSO-d$_6$) δ 10.32 (s, 2H), 10 (s, 1H), 8.53 (s, 2H). ^{13}C NMR (50 MHz, DMSO-d$_6$) δ 192.18, 191.3, 166.49, 137.82, 128.72, 124.63.

HTA

HTA
Synthesis of RT-COP:

In a Schlenk tube, 2,4-dihydroxy-1,3,5-triformylcarbaldehyde (DHTA) (31 mg, 0.16 mmol) and 3,5-diamino-1,2,4-triazole (24 mg, 0.24 mmol) was taken followed by addition of 1 mL dimethyl acetamide, 1 mL mesitylene, 1 ml dioxane and 0.3 mL 6 M acetic acid. Then the mixture was sonicated for 30 min to get a homogeneous dispersion. Then, the tube was flash frozen using liquid N_2 followed by degassing using vacuum pump for three continuous cycles. Then the tube was kept at 120 ˚C in an oil bath for 3 days to obtain red precipitate powder. The powder was filtered and washed with methanol, THF followed by Soxhlet extraction with methanol for 2 days. Finally, the powder was collected and dried in an oven at 110 ˚ C.
Synthesis of PT-COP:

In a Schlenk tube, 2-hydroxy-1,3,5-triformylcarbaldehyde (HTA) (35 mg, 0.2 mmol) and 3,5-diamino-1,2,4-traizole (30 mg, 0.3 mmol) was taken followed by addition of 0.5 mL dimethyl acetamide, 1 mL mesitylene, 1 ml dioxane and 0.3 mL 6 M acetic acid. Then the mixture was sonicated for 30 min to get a homogeneous dispersion. Then, the tube was flash frozen using liquid N_2 followed by degassing using vacuum pump for three continuous cycles. Then the tube was kept at 120 ˚C in an oil bath for 3 days to obtain yellow precipitate. The powder was filtered and washed with methanol, THF followed by Soxhlet extraction with methanol for 2 days. Finally, the powder was collected and dried in an oven at 110 ˚C.
Instrumentation.

To analyze the crystallinity of covalent organic polymers, Powder X-ray diffraction (PXRD) analysis was carried out with Bruker D8 Advances instrument with Cu-Kα (λ = 1.5406 Å) radiation in the 2θ range from 5° to 60° with an acceleration voltage of 40 KV. To confirm structural analysis, Bruker NMR400 instrument was used. Field emission scanning electron microscope (SEM Jeol JSMIT300) was used to further characterize the detailed surface morphology. X-ray photoelectron spectroscopy (XPS) was performed to determine the bonding configuration and surface elemental composition using spectrometer (K-Alpha 1063) instruments in an ultrahigh vacuum chamber (7×10^{-9} torr). All these spectra mentioned above of the synthesized materials were measured under ambient condition. All the condition is maintained throughout the experiment. Fourier transform Infrared spectroscopy (FT-IR) was carried out on FTIR BRUKER VERTEX 70 Sr. 2236 FTIR instrument at room temperature.

Electrode preparation:

The catalyst ink was prepared by dispersing 5 mg of RT-COP catalyst and 5 mg of activated carbon (acetylene black) in 1 mL of water and isopropanol (1:1) through ultrasonication for 45 minutes to create a homogeneous mixture. Before drop casting the material, the glassy carbon (GC) electrode, and rotating ring-disk electrode (RRDE) were thoroughly polished with 1, 0.3, and 0.05 μm alumina powder and rinsing ultrasonically in deionized (DI) water. The optimized mass of the synthesized catalyst ink was drop-cast onto the electrode surface and vacuum-dried for 12 hours. The catalyst inks for other PT-COP material were prepared using the same method. For comparison, the Pt/C (20 wt%) catalyst was prepared by dispersing 10 mg of Pt/C in a water and isopropyl alcohol mixture (1:1) containing 5% Nafion, followed by 45 minutes of ultrasonication. All electrochemical measurements were conducted at room temperature.

Electrochemical Measurements

Electrochemical characterizations were performed in a three-electrode cell setup using a Metrohm multichannel Autolab (M204) electrochemical workstation at room temperature. A catalyst coated rotating ring-disk electrode (RRDE; GC disk area 0.196 cm^2; Pt ring area 0.041 cm^2)

was used as working electrode, and Ag/AgCl (3 M KCl) as reference electrode. The graphite rod used as counter electrode in this study for ORR analysis. All the potentials were calibrated vs reversible hydrogen electrode (RHE) by using the equation:

E_{RHE} **(V)= $E_{Ag/AgCl\ (3\ M\ KCl)}$ (in V) + (0.059 $\times$ pH) + 0.210 V**   Eq. (1)

All the electrochemical measurements cyclic voltammetry (CV) and linear sweep voltammetry (LSV), chronoamperometry were carried out in 0.1 M KOH (pH >13) solution for ORR that was saturated with O_2 for 30 min prior to the reaction and also during the reaction O_2 saturation was maintained. As the system achieved equilibrium, the data was logged at the scan rate of 10 mV s^{-1}. During LSV test, the rotation speed of the working electrode (WE) was increased from 625 to 2500 rpm at the scan rate of 10 mV s^{-1}. The number of electrons transferred (n) per O_2 molecule, diffusion-limiting (J_L), and kinetic current densities (J_K) were calculated from the slopes (B) of the best linear fit lines of K-L plot using KL equation which is given by:

$$\frac{1}{J} = \frac{1}{JL} + \frac{1}{JK} = \frac{\frac{1}{\frac{1}{2}} + \frac{1}{JK}}{B\omega^2}$$ Eq. (2)

Where j is the measured current density, kinetic current densities (J_K), diffusion-limiting (J_L), and the number of electrons transferred (n) per O_2 molecule, ω is the angular velocity of the disk (ω = 2πN, N is the linear rotation speed), and B is the Levich slope.[3,4]

B is given by:

$$B = 0.62nFC0\ D0^{2/3}\vartheta^{-1/6}$$ Eq. (3)

$$JK = nFkC0$$ Eq. (4)

Where J is the measured current density, J_L and J_K are the diffusion-limiting and kinetic current densities, n is the overall number of electrons transferred in oxygen reduction reaction, C_0 is the bulk concentration of O_2 in the solution, ϑ is the kinematic viscosity of the electrolyte (1.09×10^{-2} $cm^2\,s^{-1}$), D_0 is the diffusion coefficient of O_2 in 0.1 M KOH ($1.93 \times 10^{-5}\,cm^2\,s^{-1}$) and F is the Faraday constant (F = 96485 C mol^{-1}).

The number of electrons transferred (n) and H_2O_2 production yield is calculated from the RRDE measurement using equations:

$$n = 4 \times \frac{I\mathbf{D}}{I\mathbf{D} + \dfrac{I\mathbf{R}}{N}}$$

Eq. (5)

$$\%H2O2 = 200 \times \frac{\dfrac{I\mathbf{R}}{N}}{\dfrac{I\mathbf{R}}{N} + I\mathbf{D}}$$

Eq. (6)

where n is the number of electrons transferred (n) during the ORR process, I_R and I_D are the absolute value of the ring and disk currents, respectively. Here N is the current collection efficiency of the Pt ring (0.249 in this work).[1,2]

The electrochemical surface area (ECSA) of these COP materials were calculated by using a three-electrode system in alkaline media. To measure it cyclic voltammetry curve at different scan rates from 10 mV s^{-1} to 100 mV s^{-1} were taken in 0.1 M KOH electrolyte solution. The double layer capacitance (C_{dl}) of all these materials were measured through CV curves in a non-faradaic region with various scan rates (10, 20, 40, 60, 80, and 100 mV s^{-1}) by the following equation given below.

$$ECSA = \frac{C_{dl}}{C_s}$$

Eq. (7)

Where C_s = 0.040 mF is the specific capacitance.

The in-situ electrochemical Fourier transform infrared (FT-IR) spectroscopy of the RT-COP catalyst:

The in-situ FT-IR spectroscopic study for the ORR intermediate detection with RT-COP material have been performed in Argon and O_2 saturated alkaline media. The chronoamperometry technique was unutilized at different potentials (1.0, 0.90, 0.80, 0.70, 0.60, 0.50, and 0.40 V vs RHE) in Argon and O_2-saturated alkaline electrolyte. The in-situ FTIR spectra was recorded and intermediate products detected as explained in the main manuscript file. The peak intensity enhancement with the potential from 1.0 V to 0.4 V clearly indicates the formation of the water as a final product in the ORR catalysis.

Theoretical Study:

Methodology: In this study, all Density Functional Theory (DFT) calculations were performed using the Gaussian16 Rev B.01 quantum chemical software package.[3] Geometry optimizations were carried out employing the Grimme's dispersion-corrected B3LYP functional (B3LYP-D3).[4,5] To describe the atomic species, the 6-31G** basis set was used for carbon, hydrogen, nitrogen, and oxygen atoms. Frequency calculations were performed to confirm the nature of the stationary points on the potential energy surface (PES) and to provide thermal corrections to the free energy.[6,7] The optimized geometries were visualized using Chemcraft (version 1.6). Further analysis, including Natural Bond Orbital (NBO) and Wiberg Bond Index (WBI) calculations, was conducted at the B3LYP/Def2-TZVP level of theory, incorporating Grimme's GD3 dispersion corrections. The NBO analysis provided insights into the electronic structure and bonding characteristics, while the WBI analysis offered quantitative bond index values to assess bond orders. The zero-point vibrational energy (ZPVE) corrected complexation energies were calculated using the following expression:

$$\Delta E_{Comp}^{ZPVE} \ = \ \Delta E_{Comp}^{ZPVE} - E_{COP}^{ZPVE} - E_{O2}^{ZPVE} \qquad\qquad Eq.\,8$$
