Computational methods

The calculations in this work were performed using spin-polarized density functional theory (DFT) as implemented in the Vienna Ab-initio Simulation Package (VASP).^{1,2} The electron-ion interactions were described by the projector augmented wave (PAW) method³ and The Perdew-Burke-Ernzerhof (PBE) functional was used as an exchange-correlation functional approximation.^{4,5} The van der Waals (vdW) correction proposed by Grimme (DFT-D2) was employed to describe long-range vdW interactions.⁶ The crystal structures of boron phosphide (BP) and boron arsenide (BAs) are modeled based on their bulk properties. Lattice constants are $a=b=c=4.55\text{ \AA}$ and $a=b=c=4.77\text{ \AA}$. Both materials adopt a cubic structure, which belongs to the space group F-43m. The BP/BAs (110) surfaces were modeled with 3×2 supercells, and six atomic layers were used. During structure optimization, the adsorbates and the 4 topmost layers were allowed to relax in all directions while the 2 bottom layers were fixed at the optimized bulk positions (See Fig. S10). A plane wave basis set with an energy cutoff of 450 eV was used. In geometry optimizations, all the atomic coordinates were fully relaxed up to the residual atomic forces smaller than 0.02 eV/ \AA , and the total energy was converged to 10^{-4} eV. The vertical separation between periodic slabs was more than 16 \AA in all cases. The Brillouin zones of all surfaces were sampled with $5\times 5\times 1$ Monkhorst-Pack grids. The climbing-image nudge elastic band (NEB) method⁷ was employed to locate the minimum energy paths. All intermediate images of each CI-NEB simulation were relaxed until the forces converged to 0.05 eV/ \AA . Ab initio molecular dynamics (AIMD) simulations were performed in the canonical ensemble with a time step of 1.0 fs. The temperature was set to 500 K using the Nose-Hoover method.⁸ The AIMD simulations of the BP and BAs (110) surfaces in an aqueous electrolyte environment containing alkali metal ions (Na^+) and 30 explicit water molecules.

The free energy changes at each electrochemical step involving a proton-electron transfer were computed based on computational hydrogen electrode (CHE) model^{9,10}, in which the free energy of ($H^+ + e^-$) equals to $1/2H_2(g)$ for standard hydrogen electrode (SHE). The free energy of adsorbates

and non-adsorbed gas-phase molecules is calculated as $G = E_{DFT} + E_{ZPE} + \int C_p dT - TS$, where E_{DFT} is the electronic energy calculated by DFT, E_{ZPE} is the zero-point energy (ZPE), C_p is heat capacity, T and S is temperature and entropy, respectively.

Calculation methods of free energy difference:

$$\Delta G = \Delta E + \Delta E_{ZPE} - T\Delta S + \int C_P dT$$

The ΔE_{ZPE} , $T\Delta S$ and $\int C_P dT$ for each reaction intermediates can be calculated by the following equations, respectively:

$$E_{ZPE} = \frac{1}{2} \sum_i h\nu_i$$

$$-TS = k_B T \sum_i \ln \left(1 - e^{-\frac{h\nu_i}{k_B T}} \right) - \sum_i h\nu_i \left(\frac{1}{e^{\frac{h\nu_i}{k_B T}} - 1} \right)$$

$$\int C_P dT = \sum_i h\nu_i \left(\frac{1}{e^{\frac{h\nu_i}{k_B T}} - 1} \right)$$

In the equations above, h , ν and k_B are Planck constant, vibrational frequencies, and Boltzmann constant, respectively. Besides, only when we calculate the free energy of reaction intermediates, the zero-point energy, entropy, and enthalpy are needed to calculate.

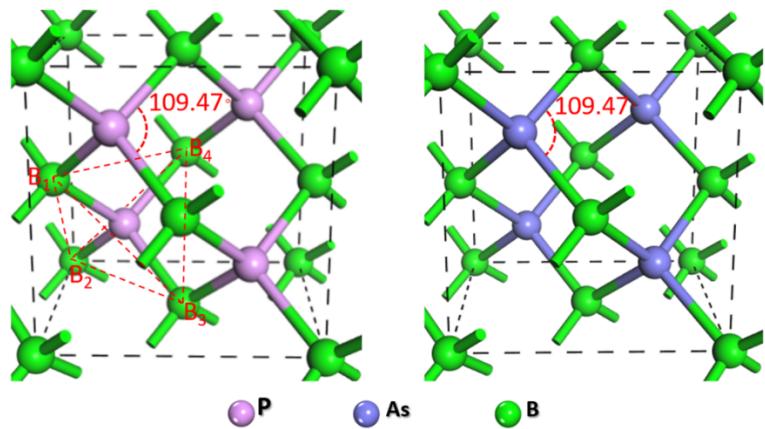

Fig. S1 The structure of BP and BAs unit-cell. The cubic BP and BAs present a typical sp³ hybridization with a tetrahedral configuration and a bond angle of 109.47°.

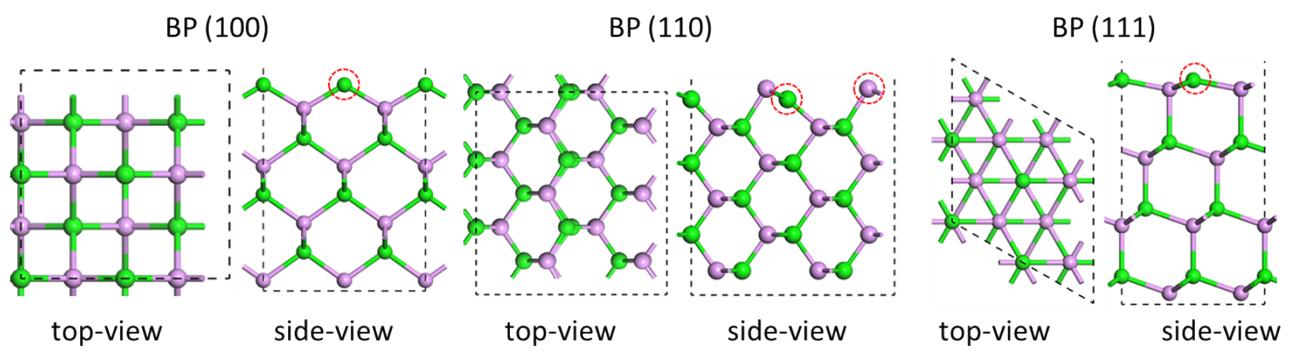

Fig. S2 Schematic atomic structures of (a) the (100) surface, (b) the (110) surface, and (c) the (111) surface of cubic BP. The red circles represent the exposed sites with surface dangling bonds.

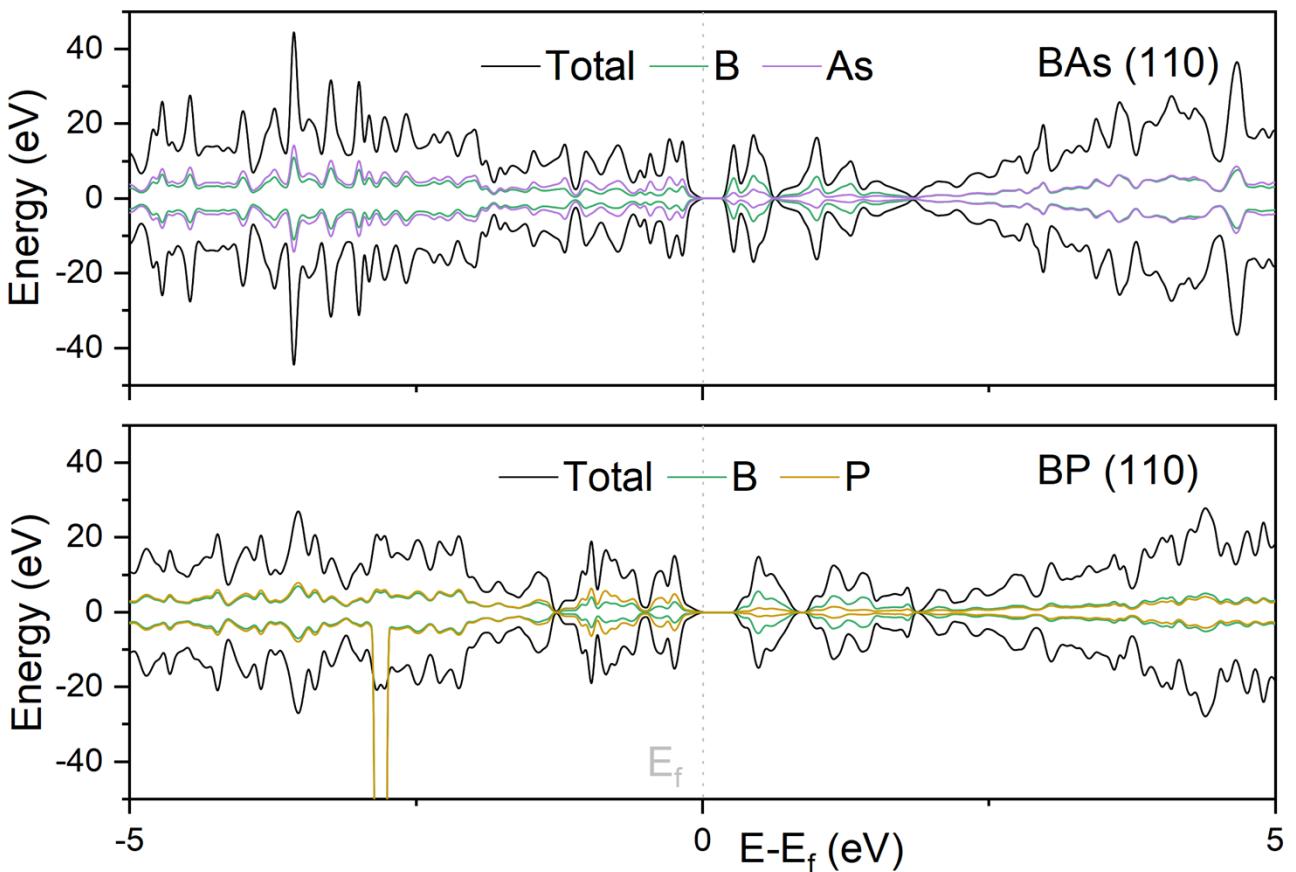

Fig. S3 The PDOS of BAs and BP (110) surface. A high density of states near the conduction band minimum and the valence band maximum, which suggests that the carrier mobility should be quite favorable in these regions despite the semiconducting nature.

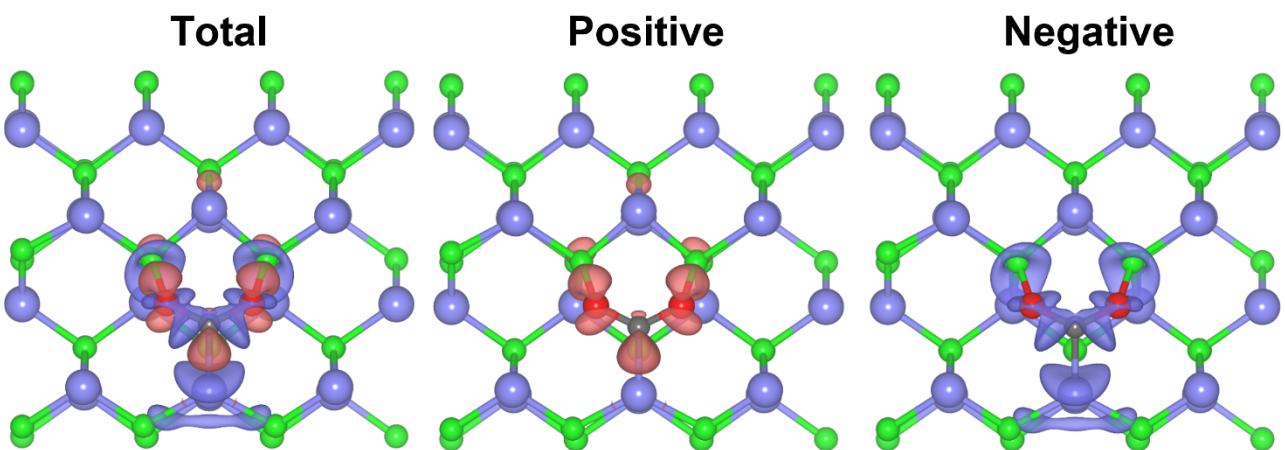

Fig. S4 Configuration and charge density difference for CO_2 molecule adsorbed on BAs (110)

surface and the isosurface value is set at 8.5×10^{-4} e/Bohr³. Red represents electron accumulation and blue refers to electron depletion.

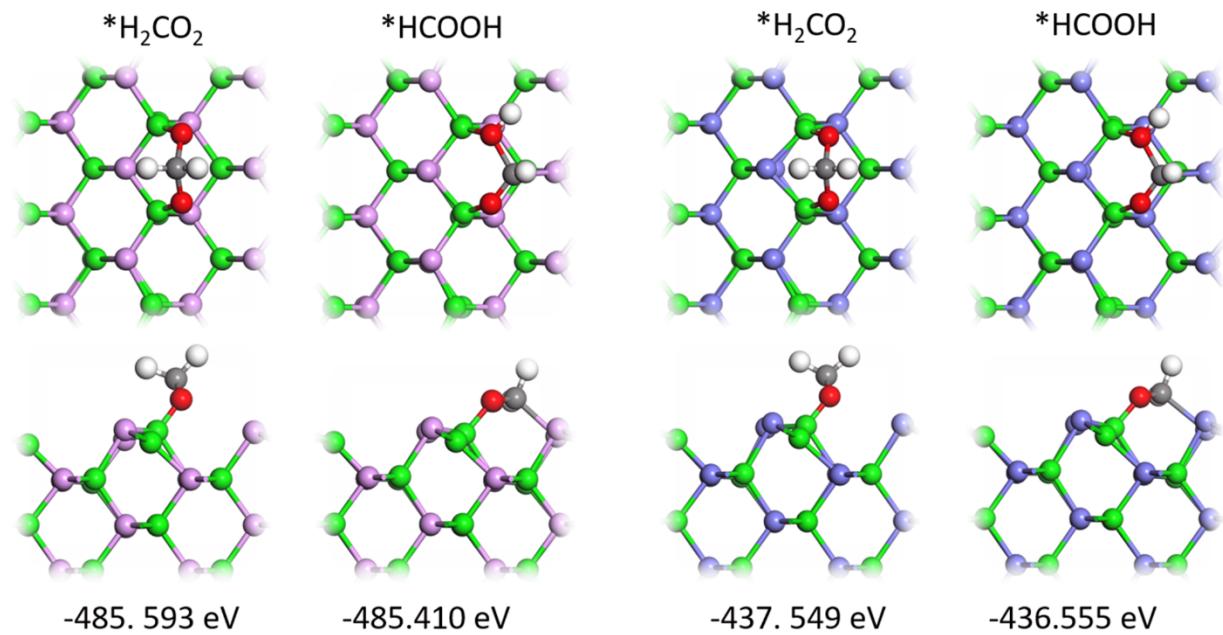

Fig. S7 Structures (top and side views) of H_2CO_2 and HCOOH adsorbed on BP and BAs (110) surface.

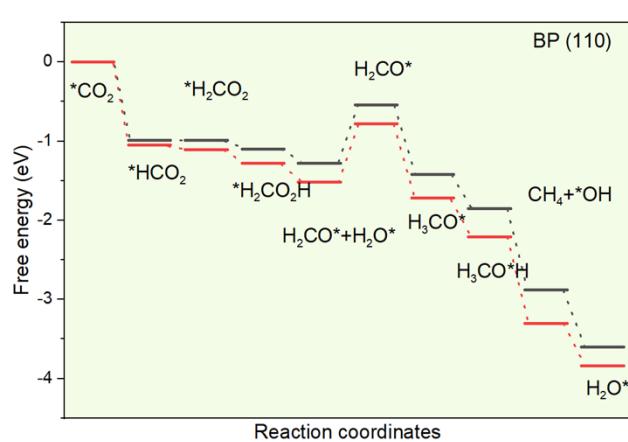

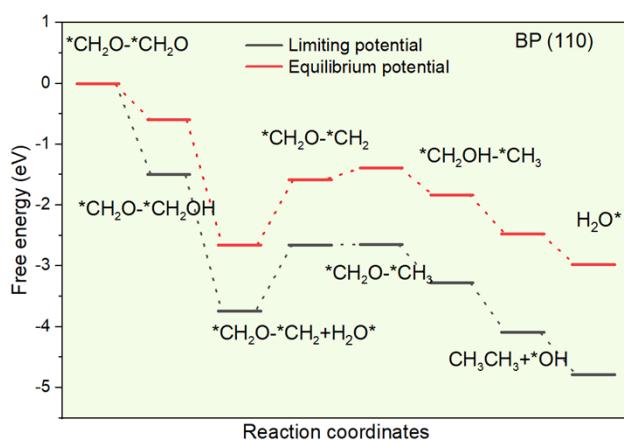

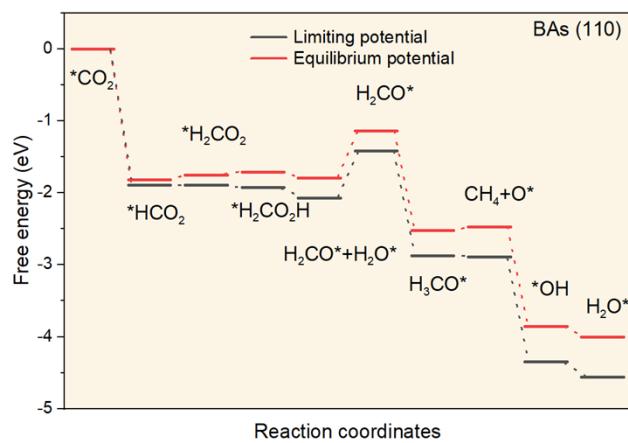

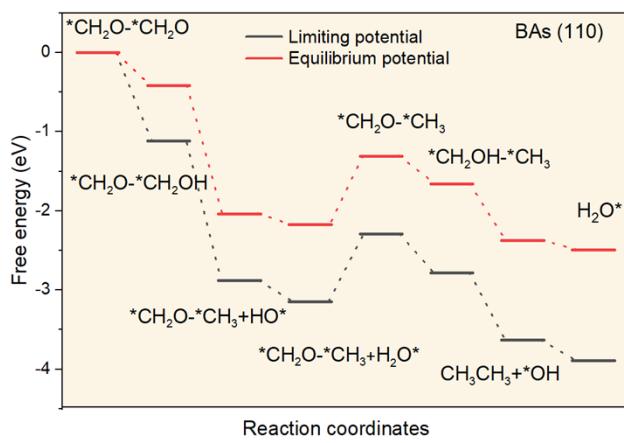

Fig. S8 Free energy diagrams for CH₄ and C₂H₆ formation from the initial CO₂ activation at equilibrium and limiting potential conditions.

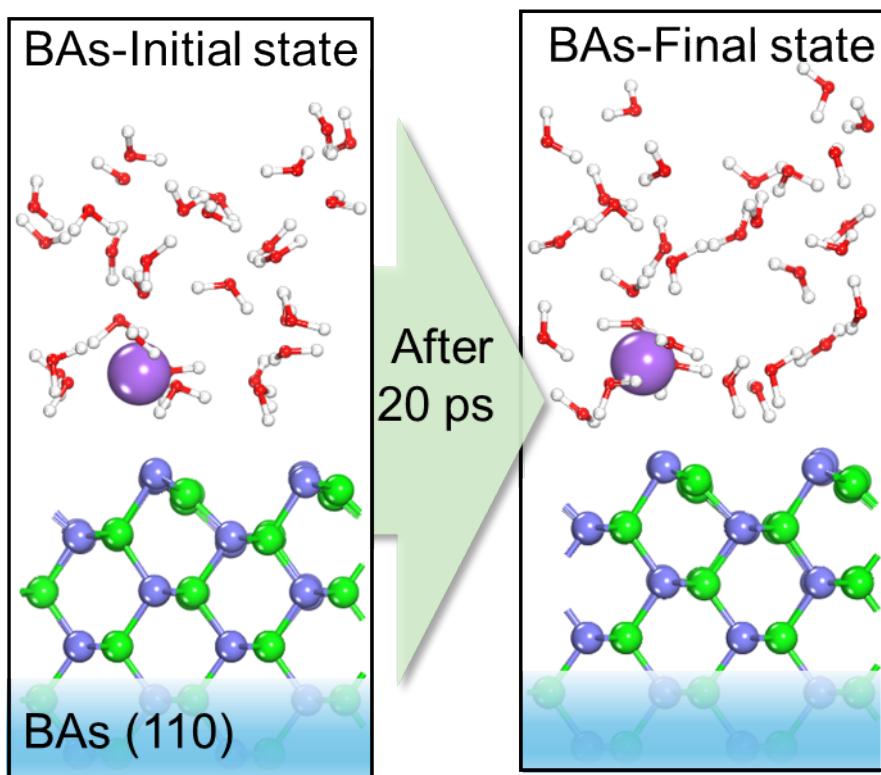

Fig. S9 AIMD simulations of BAs (110) under electrochemical conditions. Oxygen, hydrogen, boron, arsenic, and Na atoms are red, white, light green, dark blue, and dark purple, respectively.

Table S1 The dissolution potential of P and As for BP and BAs (110) surface, respectively.

Dissolution process	dissolution potential (V)
P dissolution	-4.43
As dissolution	-3.65

The dissolution potentials of surface P and As atoms is simply estimated by DFT calculations.

The dissolution process can be described by the following chemical reactions:

In these reactions, surface P and As atoms are reduced to PH_3 and AsH_3 , respectively, through proton-coupled electron transfer. The dissolution potential (U_{diss}) is defined as: $U_{\text{diss}} = -\Delta G/e$. Our calculations show that the dissolution potentials for both P and As are very high, as summarized in Table S1. This indicates that a significant potential is required for the electrodissolution of P and As, suggesting that the materials are thermodynamically stable under the reaction conditions.

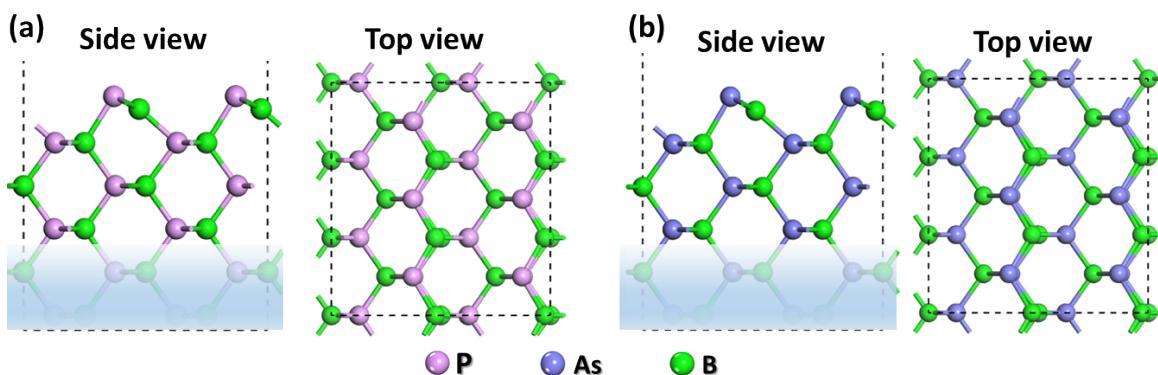

Fig. S10 Schematic atomic structures of (a) the (110) surface of cubic BP and (b) the (110) surface of cubic BAs. The layers inside the blue rectangle regions are fixed to bulk positions while other layers are relaxed.
