SHAPE analysis of alkali metals centers in 1-3

The coordination environment of the tetra-coordinated Li-ion in complex **1** adopts a tetrahedral shape, while the $\text{Na}_1(\text{I})$ exhibits an octahedron environment, and $\text{Na}_2(\text{I})$ displays a vacant trigonal bipyramid. The geometry of the $\text{K}(\text{I})$ in compound **3** takes on a capped trigonal prism configuration. These geometries were analyzed by SHAPE 2.1 software. Continuous Shape measurements reveal that the core geometries of the alkali metal center in all three complexes (**1-**

3) differ, with minimal deviation from ideal *Td* symmetry in compound **1**, *Oh* and *C_{3v}* symmetry in compound **2**, and similarly *C_{2v}* symmetry in compound **3**.

SEM morphological studies of alkali metals tert-butyl phosphonates 1-3

The morphological features of alkali metal tert-butyl phosphonate compounds **1**, **2**, and **3** were investigated by a field emission scanning electron microscope (FEG_SEM). The FEG-SEM images revealed a layered sheet kind of morphology of compounds **1**, **2**, in (Fig. S10 and S11) and **3** was shown (Fig. S12), which has been further corroborated by the single-crystal X-ray diffraction experiments (vide supra). Comparing the surface roughness of compounds **2** and **3** exhibited a higher degree of roughness compared to compound **1**. The average size of the synthesized sheet-like structures ranged from a few micro to 15 μm . Notably, the compound **3** exhibited a unique feature where the single sheet rolled up to form a tubular structure reminiscent of carbon nanotubes (Fig. S13) Furthermore, SEM-EDX mapping confirmed the uniform distribution of the respective elements throughout the layered sheet structure of compounds **1**, **2**, and **3**, indicating the consistent composition and structure of these materials.
