General information

Experiments were performed under inert conditions using standard Schlenk techniques or a glove box (Vacuum Atmospheres Company) as appropriate. Subsequent manipulation of air-stable products was carried out under ambient conditions. Dichloromethane (DCM), acetonitrile, diethylether and *n*-hexane were purified using a solvent purification system, deoxygenated and stored over 4 Å molecular sieves prior to use. Chloroform-d (CDCl_3), 1,2-dichlorobenzene (DCB), *tert*-butylmethylether (TBME), dimethylformamide (DMF) and 1,2-difluorobenzene (DFB) solvents were stirred over CaH_2 at room temperature under nitrogen atmosphere overnight prior to distillation under reduced pressure. Tetrahydrofuran (THF) was distilled under nitrogen from sodium and benzophenone and stored over 4 Å molecular sieves. Glassware for reactions were oven-dried overnight prior to use in experiments. Column chromatography using silica (230-400 mesh) was carried out using analytical grade eluent mixtures of *n*-hexane and ethyl acetate. ^1H , ^{13}C , ^{19}F and ^{31}P NMR spectra were all carried out at 298 K and recorded using Bruker AV-400 and AV-500 spectrometers. The chemical shifts (δ) for ^1H and $^{31}\text{P}\{^1\text{H}\}$ spectra were referenced to solvent, bis(triphenylphosphine)iminium tetrakis(pentafluorophenyl)borate {[PPN][BAr F_{20}]}) or hexamethylphosphoramide (HMPA). The starting materials Na[B(C₆F₅)₄]¹ and K[B(C₆F₅)₄]² were prepared using reported methods. All other reagents were obtained commercially and used as received.

Order in PPh₃

Na[BAr^F₂₀] (35.0 mg, 1.0 equiv, 0.05 mmol) and PPh₃ (0.25, 0.5, 1.0 equiv) were dissolved in DFB (0.5 mL). The solution was added to a J. Young's NMR tube containing BnCl (6.2 mg, 1.0 equiv, 0.05 mmol) and [PPN][BAr^F₂₀] (30.3 mg, 0.025 mmol) as an internal standard. The reaction was monitored at 298 K by ³¹P NMR spectroscopy to determine the concentration of the product [BnPPh₃][BAr^F₂₀] and the remaining starting material.

PPh_3 (13.0 mg, 1.0 equiv, 0.05 mmol) and $\text{Na[BArF}_{20}\text{]}$ (35.0 mg, 1.0 equiv, 0.05 mmol) were dissolved in DFB (0.5 mL). The solution was added to a J. Young's NMR tube containing a combinations of compounds **1a**, **1b**, **1c**, **1d** and **1e** such that the combined concentration of compounds **1** was equal to 1.0 equiv. The reaction was monitored at 298 K by ^1H and ^{31}P NMR spectroscopies to determine the ratio of the products (and thus their relative rate values).

Computational Studies

Computational methodology

To gain insight into the mechanism of formation of the heterocyclic compounds, we performed DFT calculations with the Gaussian 16 suite of programs (Revision A.03).³

The calculations were performed using the range-separated hybrid dispersion-corrected ω B97X-D exchange-correlation functional.⁴ The solvation effects were taken into account by computing the solvation free energies employing the SMD implicit solvation model (solvent: Dichloromethane $\rightarrow \epsilon = 8.93$).⁵ Geometry optimisations and transition state locations were performed in solution phase utilizing the SMD model. All the converged geometries were analysed by vibrational frequency calculations to identify the nature of the obtained structures. The vibrational analysis revealed that all located transition states possess only one negative Hessian eigenvalue, while no imaginary frequencies were obtained for the reported minima.

The formula used to calculate the free energy: $G = E_0' + (G_0(\text{DCM}) - E_0(\text{DCM})) + \Delta G_{\text{conc}}$. The reported Gibbs free energies were obtained by combining ω B97X-D/Def2TZVPP electronic energies (E_0') with the thermal and entropic contributions computed at the ω B97X-D/Def2SVP level at T = 298.15 K ($G_0 - E_0$).⁶ The $G_{\text{sol}}(\text{DCM})$ is the solution-phase Gibbs free energy, which was derived from a single point energy calculation at the ω B97X-D/Def2SVP level for the geometry optimized in solution phase by employing the SMD model. The value of ΔG_{conc} (0.0030119 Hartree at 298.15 K ≈ 1.89 kcal/mol) corresponds to concentration correction to the Gibbs free energy when shifting from ideal gas standard state ($p = 1$ atm) to the standard concentration in solution phase ($c = 1$ mol/dm³). The conformational analysis was carried out in the MacroModel software (Release 2017-1).⁷

Cl anion removal

The thermodynamics of the pathway involving the formation of benzylic carbocation was also considered (Figure S10). The free energy change associated with the C-Cl bond cleavage in the benzyl chloride was computed to be 183.1 kcal/mol, hence, the spontaneous Cl⁻ anion dissociation is highly unlikely under the applied conditions.

The DFT computations estimated that the reaction, resulting in NaCl and the complex wherein the benzylic carbocation is positioned in close proximity of the [BAr^F₂₀]⁻ anion, was thermodynamically still rather unfavorable ($\Delta G = 30.6$ kcal/mol). The respective transition state is expected to lie higher than the product side. Therefore, the Na[BAr^F₂₀]-assisted C-Cl bond cleavage can be excluded as well.

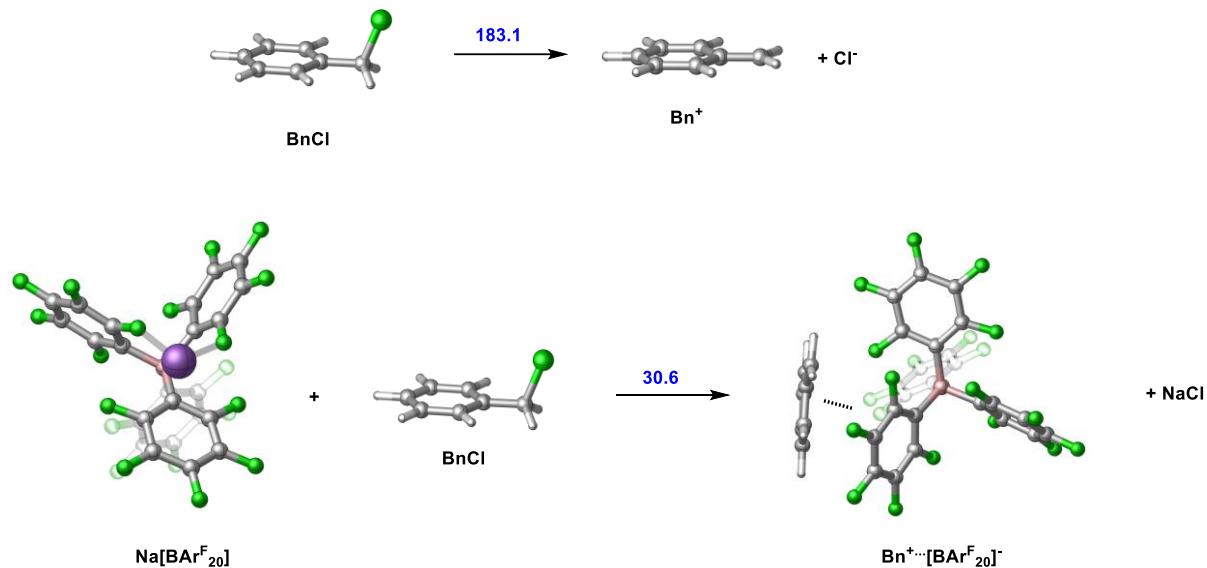

Figure S10. Gibbs energy changes associated with the removal of Cl anion.

Transition states of C-Cl cleavage

Guided by the computational results above, we assessed a pathway in which PPh₃ is involved in the C-Cl bond-breaking step as a nucleophile. At the outset, we chose the monomeric state of the Na[BAr^F₂₀], as a possible reference state in our calculations. The barrier for C-Cl cleavage was calculated by computing the free energy difference between the respective TS and the Na[BAr^F₂₀] reference state. Considering the large conformational space, an extensive conformational search was performed for the transition states, and some representative examples are shown in Figure S11. These TSs correspond to the formation of the loosely bound complex [Bn-PPh₃]⁺...NaCl...[BAr^F₂₀]. The lowest barrier related to C-Cl activation is estimated to be 21.9 kcal/mol with respect to the separate state Na[BAr^F₂₀]⁻ + PPh₃ + BnCl, which points to a kinetically feasible C-Cl activation.

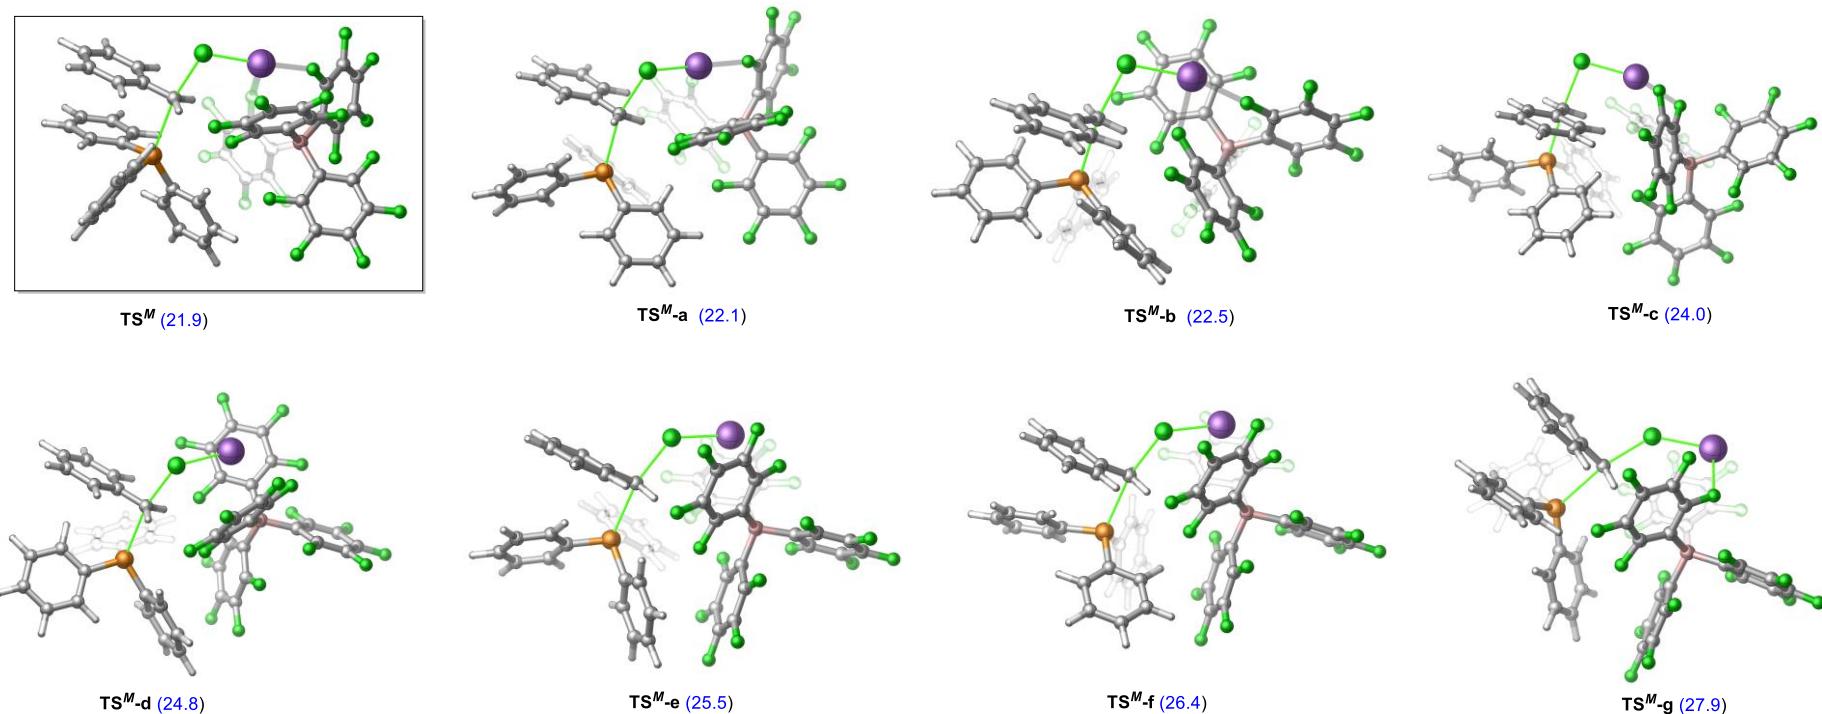

Figure S11. DFT-optimized conformers of TS^M transition state. Relative stabilities are given in parenthesis (in kcal/mol) with respect to separate state $\text{Na}[\text{BAr}^{\text{F}}_{20}]^- + \text{PPh}_3 + \text{BnCl}$.

Dimerization of $\text{Na}[\text{BAr}^{\text{F}}_{20}]$

Based on our previous experience, we examined the possibility of a dimeric form of the $\text{Na}[\text{BAr}^{\text{F}}_{20}]$ species. In the dimer $\text{Na}[\text{BAr}^{\text{F}}_{20}] \cdots \text{Na}[\text{BAr}^{\text{F}}_{20}]$, one of the Na^+ ions connects the two $\text{BAr}^{\text{F}}_{20}$ -fragments, which may be retained in the solution to some extent. Various conformers were identified, shown in Figure S12 along with free energy change associated with the dimerization. The computed data suggest that the dimerization is slightly exergonic (-2.4 kcal/mol), and the existence of the dimeric form cannot be excluded.

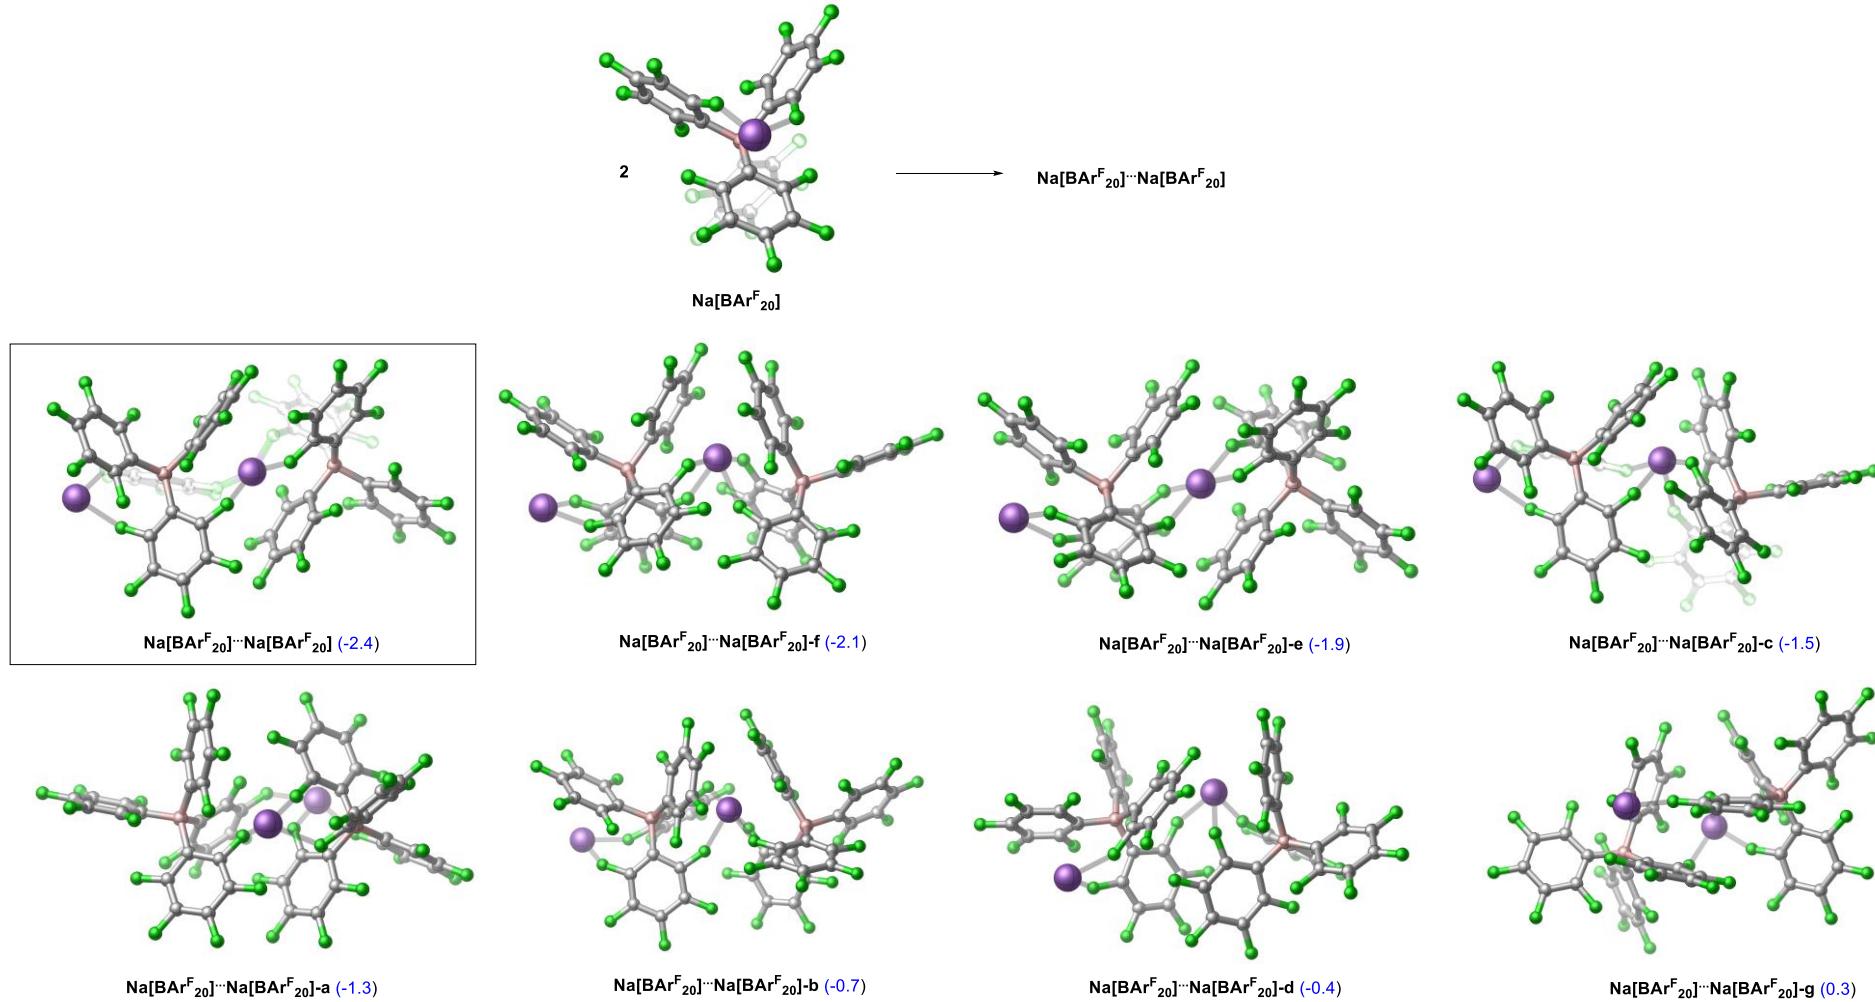

Figure 12. Gibbs energy changes associated with the dimerization of $\text{Na}[\text{BAr}^{\text{F}}_{20}]$ species are given in parenthesis (in kcal/mol).

PPh₃ coordination to Na[BAr^F₂₀]

Next, DFT calculations were carried out to estimate the relative stability of the complex PPh₃···Na[BAr^F₂₀] in the solution phase. The coordination was predicted to be favored by 1.8 kcal/mol (Figure S13), thus, for the monomeric pathway, the PPh₃···Na[BAr^F₂₀] complex was used as the reference state (see Figure 4B in the main text).

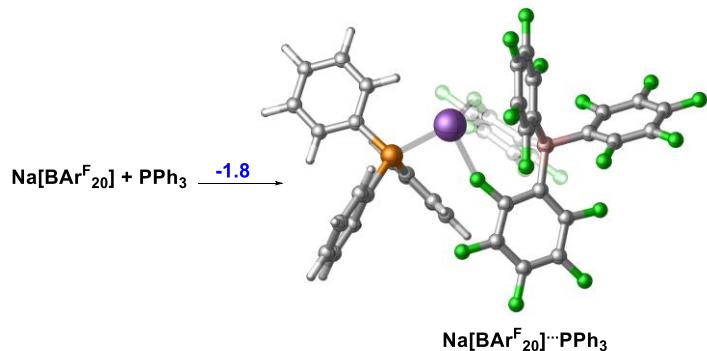

Figure S13. Gibbs energy change associated with the **PPh₃** coordination to **Na[BAr^F₂₀]**.

Similarly to the monomeric state, the thermodynamics of the PPh₃···Na[BAr^F₂₀]···Na[BAr^F₂₀] formation was computed (Figure S14). The formation of the adduct is only slightly exergonic (-0.8 kcal/mol), yet, this state was used as a reference state to estimate the overall reaction barrier on the dimeric pathway (see Figure 4C in the main text).

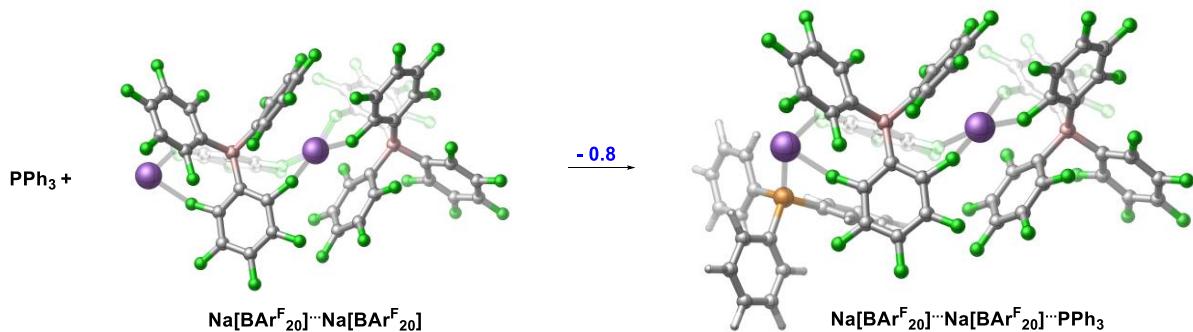

Figure 14. Gibbs energy change associated with the **PPh₃** coordination to **Na[BAr^F₂₀]···Na[BAr^F₂₀]**.

C-Cl activation without Na⁺ assistance

For Na⁺-free reaction path, the activation barrier corresponding to the nucleophilic substitution of the chloride by the PPh₃ is computed to be 29.2 kcal/mol with respect to the reference state PPh₃···Na[BAr^F₂₀] + BnCl (Figure S15). From a kinetic standpoint, this pathway is not competitive as the overall barrier height is about 6 kcal/mol higher than that of the Na[BAr^F₂₀]-assisted reaction.
