Computational details

For *S*-**1**, we need to calculate two individual Dy^{III} fragments due to their unsymmetrical structures. Complete-active-space self-consistent field (CASSCF) calculations on two individual Dy^{III} fragments for *S*-**1** (Fig. S5) on the basis of single-crystal X-ray determined geometry have been carried out with the OpenMolcas[S1] program package. Each individual Dy^{III} fragment in *S*-**1** was calculated keeping the experimentally determined structure of the corresponding compound while replacing the neighboring Dy^{III} ion by diamagnetic Lu^{III}.

The basis sets for all atoms are atomic natural orbitals from the OpenMolcas[S1] ANO-RCC library: ANO-RCC-VTZP for Dy^{III}; VTZ for close N and O; VDZ for distant atoms. The calculations employed the second order Douglas-Kroll-Hess Hamiltonian, where scalar relativistic contractions were taken into account in the basis set and the spin-orbit couplings were handled separately in the restricted active space state interaction (RASSI-SO) procedure.[S2–S3] Active electrons in 7 active orbitals include all *f* electrons (CAS (9 in 7) in the CASSCF calculation. To exclude all the doubts, we calculated all the roots in the active space. We have mixed the maximum number of spin-free state which was possible with our hardware (all from 21 sextets, 128 from 224 quadruplets, 130 from 490 doublets for Dy^{III}. SINGLE_ANISO[S4–S6] program was used to obtain the energy levels, *g* tensors, magnetic axes, *et al.* based on the above CASSCF/RASSI-SO calculations.

To fit the exchange interactions in *S*-**1**, we took two steps to obtain them. Firstly, we calculated individual Dy^{III} fragments using CASSCF/RASSI-SO to obtain the corresponding magnetic properties. Then, the exchange interaction between the magnetic centers was considered within the Lines model,[S7] while the account of the dipole-dipole magnetic coupling was treated exactly. The Lines model is effective and has been successfully used widely in the research field of *d* and *f*-elements single-molecule magnets.[S8-S9]

S-**1** has one type of $\tilde{J}$. The Ising exchange Hamiltonian is:

$$\overset{)}{H}_{exch} = -\tilde{J}\hat{\tilde{S}}_{Dy1}\hat{\tilde{S}}_{Dy1'} \tag{S1}$$

$\tilde{J} = 25\cos\varphi J$, where φ is the angle between the magnetic axes on two Dy^{III} sites, and J is the Lines exchange coupling parameter. $\tilde{S}_y = 1/2$ is the ground pseudospin on the Dy^{III} site. $\tilde{J}_{total}$ is the parameter of the total magnetic interaction ($\tilde{J}_{total} = \tilde{J}_{dip} + \tilde{J}_{exch}$) between magnetic center ions. The dipolar magnetic coupling can be calculated exactly, while the exchange coupling constant was fitted through comparison of the computed and measured magnetic susceptibilities using the POLY_ANISO program.[S4-S6]

	646.1	35.7%$|\pm5/2>$+24.8%$|\pm3/2>$+16.9%$|\pm7/2>$+10.2%$|\pm9/2>$+5.8%$|\pm1/2>$

Fig. S8. Magnetization blocking barriers of individual Dy^{III} fragments for *S*-**1**. The thick black lines represent the KDs as a function of their magnetic moment along the magnetic axis. The green lines correspond to diagonal quantum tunneling of magnetization (QTM); the blue line represent off-diagonal relaxation process. The numbers at each arrow stand for the mean absolute value of the corresponding matrix element of transition magnetic moment.

Table S4. Exchange energies E (cm^{-1}), the energy difference between each exchange doublets Δ_t (cm^{-1}) and the main values of the g_z for the lowest two exchange doublets of *S*-**1**.

|	E	Δ_t	g_z
1	0.000000000000	0.849×10^{-7}	39.439
	0.000000084949		
2	3.010867490053	0.804×10^{-7}	0.926
	3.010867570411		

Fig. S9. Calculated (red solid line) and experimental (black square dot) data of magnetic susceptibilities of *S*-**1**. The intermolecular interactions *zJ'* of *S*-**1** were fitted to –0.02 cm^{-1}.
