1. Experimental Section:

All the chemicals purchased from various suppliers were used without further purification. The L-phenylalanine derivative of 1-Naphthaleneacetic acid (**Nap-F** ester) was synthesized following conventional solution phase peptide synthetic protocols by coupling methyl ester of L-phenylalanine and 1-Naphthaleneacetic acid by using HoBt and DCC as coupling agent. The purification of the **Nap-F** ester was carried out by using petroleum ether with an increasing amount of ethyl acetate. The methyl ester of the **Nap-F** was hydrolyzed following the saponification of the ester method. The free carboxylic acid of the **Nap-F** was used for further studies. The details of synthetic protocols, purifications and their characterizations by using NMR and mass spectrometric analyses were shown in Figure S1 to Figure S16. The hydrogelation behaviour of both ^L **Nap-F** and ^D **Nap-F** and their co-assembled hydrogels were quite similar.

1.1 Two-component gelation

Nap-F along with either of the three basic amino acids L-Histidine (**H**), L-Lysine (**K**) and L-Arginine (**R**) separately were taken together in a single glass vial and the gelation study was performed as follows: i) in one vial **Nap-F** and **H** were mixed (**Nap-F_H**), (ii) in second vial **Nap-F** and **K** were mixed (**Nap-F_K**) and (iii) in third glass vial **F** and **R** were mixed (**Nap-F_R**) in different ratios to check the gelation of these samples. These suspended solutions were sonicated and heated on a hot plate until a clear solution was obtained. These hot clear solutions were kept at room atmosphere undisturbed for 5 to 10 minutes and hydrogelations were confirmed by inverted vial test method. Moreover, individually **Nap-F** does not form a hydrogel in distilled water (DW) however, in the presence of either of these basic amino acids, **Nap-F** formed two-component stable hydrogels in water (Figure 1b, 1c and 1d, Table 1).

1.2 Three-component gelation

Nap-F in combination with either of the two basic amino acids were taken and the gelation study were performed as follows: i) in one vial **Nap-F**, **H** and **K** were mixed (**Nap-F_{H-K}**), (ii) in second vial **F**, **H** and **R** were mixed (**Nap-F_{H-R}**) and (iii) in the third glass vial **F**, **K** and **R** were mixed (**Nap-F_{K-R}**) in different ratios to check the gelation of these samples. These suspended solutions were sonicated followed by heating on a hot plate until clear solutions were obtained. These hot clear solutions were kept at room atmosphere and hydrogelations were confirmed by an inverted vial test method. It was observed that individually **Nap-F** not formed hydrogel in distilled water (DW) however, in combination with either of the two basic amino acids, **Nap-F** formed three-component stable hydrogels in water (Figure 1e, 1f and 1g, Table 1).

1.3 Four-component gelation

Nap-F along with all three basic amino acids L-Histidine (**H**), L-Lysine (**K**) and L-Arginine (**R**) were taken together in a single glass vial and the gelation study have been performed. These suspended solutions (**Nap-F_{H-K-R}**) were sonicated and heated on a hot plate until clear solutions were obtained. On keeping this four-component hot solution in room atmosphere undisturbed for 5 to 10 minutes, hydrogelation was observed and confirmed by the inverted vial method. This hydrogel is also obtained in water (Figure 1h, Table 1).

The minimum gelation concentrations (MGCs) of all these hydrogels have been estimated and shown in Table 1. **Nap-F_K** at a 6:2 weight ratio forms hydrogel with MGC of 0.21 % w/v which is the lowest MGC among all these hydrogels and **NAP-F** shows the highest MGC of 0.7 % w/v. **Nap-F_H** also shows a similar MGC value of 0.22 % w/v.

1.4 Xerogel preparation

All the xerogels were prepared by freeze drying the hydrogels in the Lyophilizer and used for various experiments in powder forms.

2. Materials and methods

1-Naphthaleneacetic acid was purchased from Sigma Aldrich. L-Phenylalanine, DCC (N, N'-dicyclohexylcarbodiimide) was purchased from Molychem. HOBt (1-hydroxybenzotriazole) was purchased from Spectrochem. *p*-nitrophenyl acetate (PNP) was purchased from TCI.

3. Instrumentations, Techniques and Discussion:

3.1 Tgel measurement: Different (0.7, 0.75, 0.8, 0.85, 0.9, 0.95, 1.0) % w/v hydrogels of **Nap-F** were prepared by dissolving in phosphate buffer (PB, 50mM) of pH-7.4. All these two, three and four component hydrogelators at

0.8 % w/v concentrations were dissolved in milli Q water, by using sonication followed by heating the solution, until it dissolves completely. At three different concentrations keeping the ratio 6 : 1 : 1 for **Nap-F_{H-K}** and **Nap-F_{H-R}** and Tgels were measured. The solutions were kept at rest until it comes to room temperature. The hydrogelations of the samples were confirmed by the vial inversion test method. All these gels at 0.8 % w/v were heated in a water bath to check their melting points (Tgel, temperature at which the hydrogels were melted).

3.2 UV-Vis spectroscopy: UV-Visible spectra were recorded by using a JASCO V-550, and the bandwidth and data pitch was set at 1 nm.

3.3 X-Ray Diffraction: The xerogels were characterized by X-ray diffraction (XRD) by using a powder X-ray diffractometer (Bruker D8 Advance) with Cu-K α ($\lambda=0.154$ nm).

3.4 FT-IR Spectroscopy: IR Affinity-1 (Shimadzu, Japan) FTIR spectrophotometer was used to record IR spectra and KBr was used to prepare pellets before recording IR spectra.

3.5 CD Spectroscopic Study. The circular dichroism (CD) spectroscopic study was recorded on a JASCO J-810 circular dichroism spectrometer at room temperature. Spectra were scanned at a scan rate of 200 nm/s and 2 nm bandwidth from 190 to 500 nm and the average profile of three different scans were shown in the spectra. Baseline corrections with sample media were performed before the experiments.

3.6 FE-SEM: The gelator solutions (0.25 micromolar) were dropped cast on a glass cover slip. Leica EM ACE200 was used to coat the sample with the gold at a few nm thicknesses. The images were taken under an FEI Quanta FEG 250 scanning electron microscope.

3.7 TEM: TEM imaging were carried out by using a JEOL JEM-210 PLUS Cryogenic transmission electron microscope.

3.8 Liquid Chromatography-Mass spectrometry: This data was obtained from Agilent triple quad LCMS 6460 to determine the molecular mass of compounds in the electrospray ionization (ESI +/-) mode.

3.9 NMR: These spectra were recorded on Bruker Avance Neo 500 MHz with Cryoprobe platform, Topspin controlled console and gradient control with a resolution of 12.5 ns. CDCl₃ and DMSO-d₆ were the solvents used.

3.10 Zeta Potential: Zeta potential measurements were performed by using NanoPlus-Zeta/nano particle analyzer particulate system in water.

3.11 Catalytic Study: The molar extinction coefficient (ϵ) of *p*-nitrophenol (PNP) was estimated in water from

the slope of the linear plot between absorption maxima at 400 nm versus concentrations of the *p*-nitrophenol 3 μ L of 3 mM *p*-nitrophenyl acetate has been added individually to all these assembled systems and the progress of hydrolysis have been monitored by UV-vis spectroscopy. The Michaelis–Menten kinetics equation $v = \frac{d[P]}{dt} = \frac{K_{cat}}{K_m} [E]_0 [S]$ and double-reciprocal (Lineweaver–Burk) method with the equation $v = \frac{d[P]}{dt} = K_{cat} [E]_0 \frac{[S]}{K_M + [S]}$ were used where v is reaction rate, $[P]$ is concentration of product, $[E]_0$ is the initial enzyme concentration, $[S]$ is substrate (*p*-nitrophenyl acetate) concentration, k_{cat} is the catalytic rate constant, and K_M is the Michaelis constant. The k_{cat}/K_M values calculated from the linear fitting of the double-reciprocal (Lineweaver–Burk) plot.

3.12 Rheology: This measurement was done on Anton Paar, MCR 702e Space with a minimum torque limit of 0.5 nNm under oscillation mode and 1 nNm in rotation mode. The maximum torque limit was 230 mNm. Temperature control was performed by using P-PTD 200 and PP25/SP measuring geometry. The low shear condition was done at a strain of 0.1% and 10 rad/sec angular frequency, and the high shear condition was done at 100% strain and 10 rad/sec angular frequency. All the rheological studies of the hydrogels were performed after a week later from the date of hydrogel preparation.

3.13 Confocal Microscopy: All the hydrogelators solutions (0.5 % w/v) were dropped casted on glass slides. The self-assembled and co-assembled solutions were covered with cover slips for the confocal microscopy imaging purpose in their wet gel states. An Olympus corporation FV3000 model IX83 confocal laser scanning microscope (CLSM) was used for image capturing. A 405 nm laser diode was used as the excitation source and emission was recorded from 413–484 nm range was detected. The detector gain and amplification offset/gain were optimized based on the fluorescence intensities of the hydrogel fibrils.

3.14 pH measurements: The pHs of the catalytic solutions were measured by using THERMO SCIENTIFIC™ EUTECH™ pH meter and the calibration of the pH meter was performed by using standard pH solutions of pHs of 4, 7 and 9. The calibration error during the experiments were found to be ± 0.36 .

4. Synthesis of ^LNap-F and ^DNap-F

4.1 Synthesis of 1-Naphthaleneacetic acid-conjugated L-phenylalanine (Nap-F-OMe or Nap-F-OMe): L-phenylalanine (1.65g) was dissolved in methanol (25ml) in a round bottom flask (RBF) covered with a CaCl₂ glass guard tube. The solution was stirred inside a fume hood and kept for cooling by using ice-salt mixture bath. Once the solution was cooled down, 3-5 ml of SOCl₂ was added from the walls of the RBF and covered again with a guard tube and kept for overnight under constant stirring. The completion of the reaction has been confirmed by TLC and the methanol was distilled out until 5 ml remained followed by the addition of di-ethyl ether to the RBF and yellowish-white solid appeared inside the RBF. For extraction purposes, ethyl acetate was added and washing with Na₂CO₃ was performed. The ethyl acetate extract was dried over anhydrous Na₂SO₄ and evaporated in a vacuum to obtain 2-3 ml ethyl acetate solution of the phenylalanine methyl ester.

Now, 1-Naphthalenacetic acid (3.72g) was dissolved in dry N, N-dimethyl formamide (DMF) and kept under stirring condition to cool in an ice-salt bath. Once the solution cooled down, HOBt (1.53g) and DCC (3.09g) were added and stirred well. The final step included the addition of the ethyl acetate solution of the amino acid and kept for stirring for 2 days. The reaction mixture was diluted with ethyl acetate the filtered out to separate N, N-dicyclohexyl urea (DCU). The ethyl acetate layer was washed with 1N HCl, brine, and saturated Na₂CO₃ solution. The organic layer was then further dried over anhydrous Na₂SO₄, to obtain a yellowish product.

This product was further purified through by using silica gel column chromatography, to obtain a pure white product, which is the amino acid derivative (1-Nap-^LF-OMe) (*Nap-F-OMe*) The synthesis was confirmed by

performing LC-MS and NMR spectroscopic studies.

4.2 Synthesis of 1-Naphthaleneacetic acid-conjugated L-phenylalanine (Nap-F-OH or Nap-F-OH or Nap-F in short): Hydrolysis was performed by dissolving in methanol (10ml) and under the presence of 1N NaOH (5ml), the reaction was kept overnight. The progress of the reaction was confirmed by monitoring TLCs. Further, the methanol was evaporated and the aqueous part was washed with diethyl ether followed by acidification using 1N HCl. The aqueous layer was then extracted using ethyl acetate. The ethyl acetate extract was dried over anhydrous Na_2SO_4 and evaporated in a vacuum to obtain a white powdered product (1-Nap- L F-OH) (**NAP-F**). The synthesis has been confirmed by performing LC-MS and NMR.

Hydrolysis performed using the catalytic systems at positive mode ESI	Peaks found at m/z	Possible molecular ion and fragments corresponding to the m/z
NaOH both at 50 and 70 V (Figure S31)	107	 m/z at 107 is due to $[M+2H_2O+2H^+]/2 + H_2O+2H]^{2+}$
	117	 m/z at 117 is due to $[198+2NH_4^+]/2 + 2NH_4^+]^{2+}$
	122	m/z at 122 due to $[M+2Na]/2$ of the intermediate shown below when hydroxyl ions act as nucleophile  $+2Na]^{2+}$
	139	m/z at 139 is due to M_{PNP}^+
Histidine (H) only at 50 and 70 V (Figure S32)	107	 m/z at 107 is due to $[M+2H_2O+2H^+]/2$ as $+H_2O+2H]^{2+}$
	117	 m/z at 117 is due to $[198+2NH_4^+]/2$ as $+2NH_4^+]^{2+}$
	156	m/z at 156 is due to $[M_{Histidine}+H]^+$
Lysine (K) only at 50 and 70 V (Figure S33)	107	 m/z at 107 is due to $[M+2H_2O+2H^+]/2$ as $+H_2O+2H]^{2+}$
	117	 m/z at 117 is due to $[198+2NH_4^+]/2$ as $+2NH_4^+]^{2+}$
	147	m/z at 147 $[M_{Lysine}+H]^+$
Arginine (R) only at 50 and 70 V (Figure S34)	175	m/z at 175 is due to $[M_{Arginine}+H]^+$
	117	 m/z at 117 is due to $[198+2NH_4^+]/2$ as $+2NH_4^+]^{2+}$
	276	Diacetyl arginine+ $H_2O]^+$

Figure S31. ESI-MS of the catalytic mixture solution by Nap-F_{K-R} showing the corresponding molecular ion peak for *p*-nitrophenolate at m/z 138 and with one sodium ion at m/z 160.80. The peak at m/z 99.70 is originating may be form the acetic acid with one potassium ion. The peak at m/z 197.60 to 199 may be due to the formation of alkoxide ion intermediate (molar mass of the intermediate is 198 g mol⁻¹) due to the ester hydrolysis by hydroxyl as nucleophile.

Table S5: LC-ESI-MS analyses of the mass peaks obtained shown in Figure S31-41 in positive mode at lower voltages including 50 and 70 V.

Two (Nap-F_H , Nap-F_K and Nap-F_R), three (Nap-F_{H-K} , Nap-F_{H-R} and Nap-F_{K-R}) and four-component (Nap-F_{H-K-R}) systems (Figure S35 to 41)	225	m/z at 225 may be due to $[M_{\text{Nap-F}} + \text{PNPA} + 2\text{NH}_4^+] / 2$ or $[M_{\text{Nap-F}} + \text{PNP} + 2\text{K}^+] / 2$
	268	m/z at 225 may be due to or $[M_{\text{Nap-F}} + \text{PNP} + \text{H}_2\text{O} + 2\text{Na}^+] / 2$
	334	m/z at 334 may be due to M of the intermediate shown below when hydroxyl ions act as nucleophile  $+ \text{AcOH} + 2\text{H}_2\text{O} + \text{K}^+$ or m/z at 334 can be due to the molecular ion peak along with one hydrogen of Nap-F , $[M_{\text{Nap-F}} + \text{H}]^+$
	356	m/z at 356 can be for $[M_{\text{Nap-F}} + \text{Na}]^+$
For K containing co-assembled two (Nap-F_K), three (Nap-F_{H-K} and Nap-F_{K-R}) and four-component (Nap-F_{H-K-R}) systems (Figure S36, 38, 40 to 41)	334	m/z at 334 can be for $[M_{\text{Nap-F}} + \text{H}]^+$
For R containing co-assembled Two (Nap-F_R), three (Nap-F_{H-R} and Nap-F_{K-R}) and four-component (Nap-F_{H-K-R}) systems (Figure S37, 39, 40 to 41)	334	m/z at 334 can be for $[M_{\text{Nap-F}} + \text{H}]^+$ or it can be $[M_{\text{di-acetyl arginine}} + \text{K} + 2\text{H}_2\text{O}]^+$
For H containing co-assembled two (Nap-F_H), three (Nap-F_{H-K} and Nap-F_{H-R}) and four-component (Nap-F_{H-K-R}) systems (Figure S35, 38, 39 and 41)	334	m/z at 334 can be for $[M_{\text{Nap-F}} + \text{H}]^+$

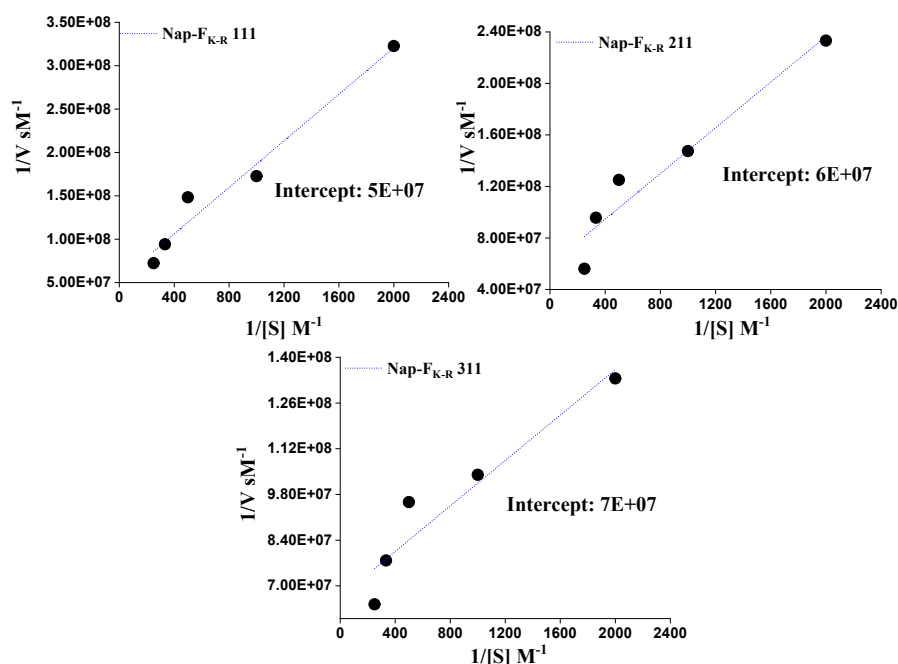

Figure S43. Lineweaver-Burk plot for the hydrolysis of PNPA using $\text{Nap-F}_{\text{K-R}}$ as catalyst keeping the amount of **K** and **R** fixed, the amount of **Nap-F** varied (a) **Nap-F** at 0.1 w/v%, (b) **Nap-F** at 0.2 w/v% and (d) **Nap-F** at 0.3 w/v% for the system 0.3 % w/v, 0.4 % w/v and 0.5 % w/v catalysts respectively.

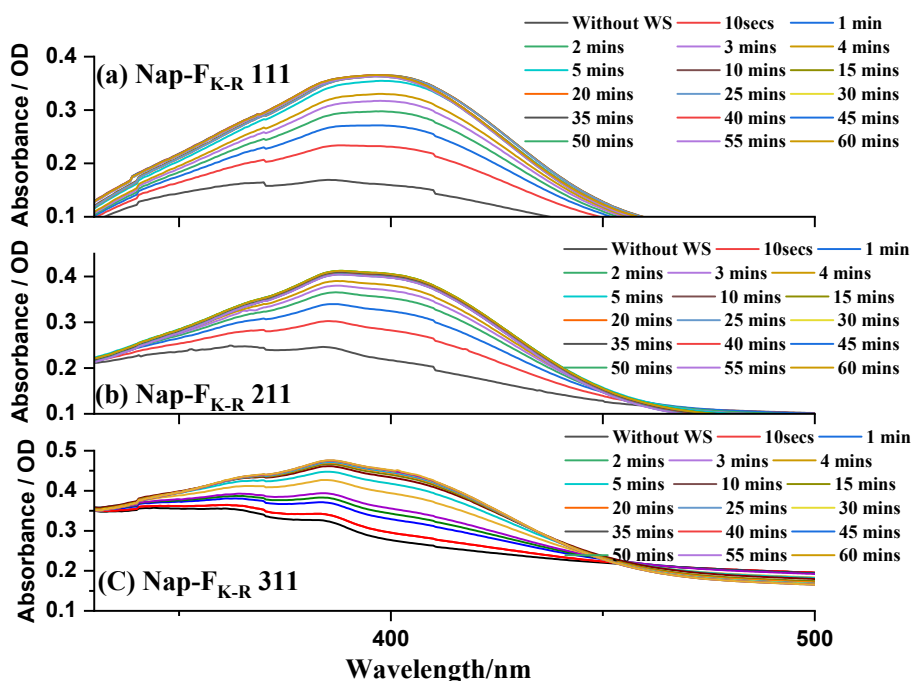

Figure S44. UV-Vis spectra for the hydrolysis of PNPA using $\text{Nap-F}_{\text{K-R}}$ as catalyst keeping the amount of **K** and **R** fixed, the amount of **Nap-F** varied (a) **Nap-F** at 0.1 w/v%, (b) **Nap-F** at 0.2 w/v% and (d) **Nap-F** at 0.3 w/v% for the system 0.3 % w/v, 0.4 % w/v and 0.5 % w/v catalysts respectively.

Figure S45. Absorbance vs Concentration plot for determination of molar extinction coefficient (ϵ) of *p*-nitrophenol at pH 9.00.

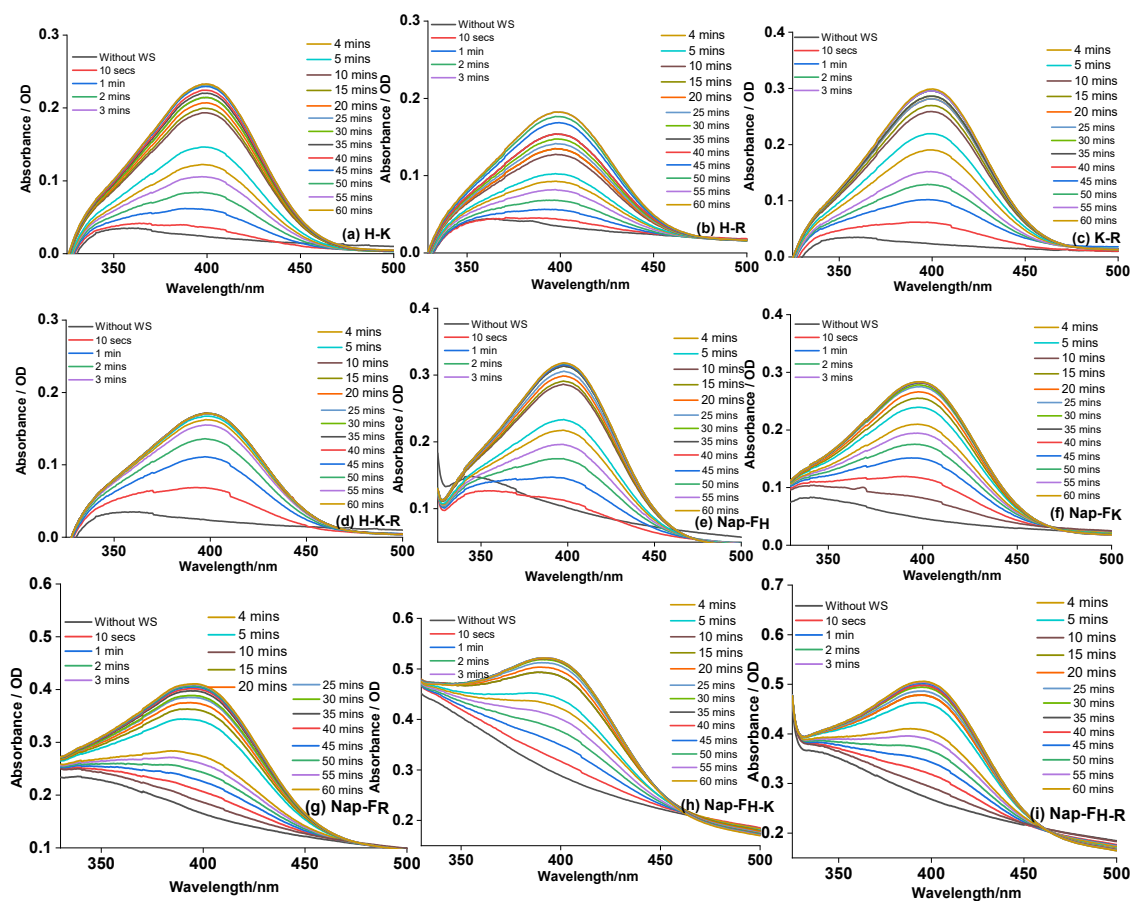

Figure S46. The progress of the *p*-NPA to *p*-NP hydrolysis reaction monitored at pH 9.00 by time dependent UV-Vis spectroscopic study for the systems including a) H-K, (b) H-R, (c) K-R, (d) H-K-R, (e) Nap-F_H, (f) Nap-F_K, (g) Nap-F_R, (h) Nap-F_{H-K}, (i) Nap-F_{H-R}, (k) Nap-F_{K-R}, and (l) Nap-F_{H-K-R}.

Figure S47. Lineweaver-Burk plot for the hydrolysis of *p*-NPA by using various systems as catalysts at pH 9.00 such as Nap-F_H, Nap-F_K, Nap-F_R, Nap-F_{H-K}, Nap-F_{H-R}, Nap-F_{K-R} and Nap-F_{H-K-R}.

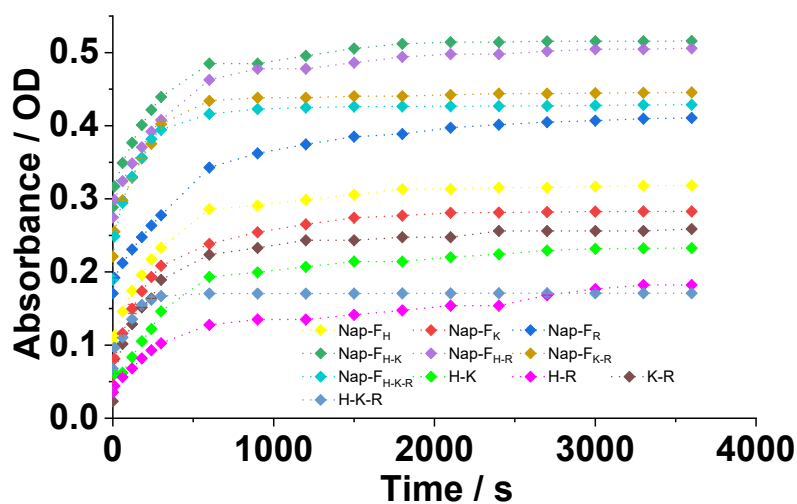

Figure 48. Absorbance versus time spectra for Nap-F_H, Nap-F_K, Nap-F_R, Nap-F_{H-K}, Nap-F_{H-R}, Nap-F_{K-R}, Nap-F_{H-K-R}, H-R, H-K, K-R and H-K-R at 0.5% w/v concentrations of pH 9.00 with 3ul working solution of NPA.

Table S6. Kinetic parameters for the hydrolysis of PNPA in the presence of catalyst systems at pH 9.00. The Michaelis–Menten kinetics equation $v = \frac{d[P]}{dt} = \frac{K_{cat}}{K_m} [E]_0 [S]$ and double-reciprocal (Lineweaver–Burk) method with the equation $v = \frac{d[P]}{dt} = K_{cat} [E]_0 \frac{[S]}{K_M + [S]}$ were used where v is reaction rate, $[P]$ is concentration of product, $[E]_0$ is the initial enzyme concentration, $[S]$ is substrate (p-nitrophenyl acetate) concentration, k_{cat} is the catalytic rate constant, and K_M is the Michaelis constant. The k_{cat}/K_M values calculated from the linear fitting of the double-reciprocal (Lineweaver–Burk) plot (Figure S47).

Catalyst	K_{cat} (s ⁻¹)	K_M (M)	K_{cat} / K_M (M ⁻¹ s ⁻¹)
H-K (2.5:2.5) (0.5% w/v)	2.02×10^{-3}	8.11×10^{-2}	2.49×10^{-2}
H-R (2.5:2.5) (0.5% w/v)	1.21×10^{-4}	5.43×10^{-3}	2.23×10^{-2}
K-R (2.5:2.5) (0.5% w/v)	1.33×10^{-4}	6.84×10^{-3}	1.95×10^{-2}
Nap-F _H (2.5:2.5) (0.5% w/v)	1.635×10^{-4}	6.06×10^{-3}	2.68×10^{-2}
Nap-F _K (2.5:2.5) (0.5% w/v)	2.40×10^{-4}	3.63×10^{-2}	6.61×10^{-2}
Nap-F _R (2.5:2.5) (0.5% w/v)	1.02×10^{-4}	3.69×10^{-3}	2.75×10^{-2}
H-K-R (1.6:1.6:1.6) (0.5% w/v)	3.17×10^{-3}	1.57×10^{-1}	2.02×10^{-2}
Nap-F _{H-K} (3:1:1) (0.5% w/v)	1.27×10^{-5}	3.0×10^{-3}	4.23×10^{-3}
Nap-F _{H-R} (3:1:1) (0.5% w/v)	3.38×10^{-4}	8.55×10^{-3}	3.95×10^{-2}
Nap-F _{K-R} (3:1:1) (0.5% w/v)	3.27×10^{-4}	7.76×10^{-3}	4.22×10^{-2}
Nap-F _{R-K-H} (2:1:1:1) (0.5% w/v)	1.62×10^{-4}	4.7×10^{-3}	3.44×10^{-2}

Figure S49. FE-SEM images at assembled solutions of pH 9.00 (50 times dilution for all samples done from 0.5 w/v % co- assembled solution) which have been used for catalytic studies (a) Nap-F_K 2.5:2.5, (b) Nap-F_{H-K} 3:1:1 and (c) Nap-F_{K-R} 3:1:1 (0.5 w/v %).
