I. General remarks

General methods: Unless otherwise noted, all reagents were obtained from commercial suppliers and used without further purification. NMR spectra were obtained on a Bruker AVANCE III 500 spectrometer. The ¹H NMR (500 MHz) chemical shifts were measured relative to DMSO- d_6 as the internal reference (DMSO d_6 : $\delta = 2.50$ ppm). The ¹³C NMR (125.72 MHz) chemical shifts were given using DMSO- d_6 as the internal standard (DMSO- d_6 : $\delta = 39.52$ ppm). Infrared (IR) spectra were recorded on a Perkin-Elmer Spectrum II IR Spectrometers using KBr pellets. X-Ray single-crystal diffraction data were collected on a Rigaku AFC-10/Saturn 724+CCD diffractometer with graphite-monochromated Mo K α radiation (λ =0.71073 Å) using the multi-scan technique. Thermal decomposition temperatures were determined by using differential scanning calorimetry (DSC) on a Mettler-Toledo TGA/DSC 1 Stare system at a heating rate of 5 °C·min⁻¹ from room temperature to 400 °C under nitrogen atmosphere. The detonation parameters, including detonation velocity and detonation pressure, were calculated by using the EXPLO5 (version 6.05.04) program. The impact and friction sensitivities were measured on a standard BAM fall hammer and a BAM friction tester¹. Hirshfeld surfaces and 2D fingerprint plots were generated by CrystalExplorer (version 17.5)². The electrostatic potential (ESP) surfaces and non-covalent interaction (NCI) analyses were analyzed and drawn by using Multiwfn (version 3.5)³ and Visual Molecular Dynamics (VMD, version 1.9.3) program suites.

 Table S3. Crystal data for compound 7 at room temperature

III. Calculation of heats of formation

Computations were performed by using the *Gaussian 09* suite of programs.⁴ The elementary geometric optimization and the frequency analysis were performed at the level of the Becke three parameter, Lee-Yan-Parr (B3LYP)⁵ functional with the 6-311++G** basis set.⁶ All of the optimized structures were characterized to be local energy minima on the potential surface without any imaginary frequencies. Atomization energies were calculated by the CBS-4M.⁷ All the optimized structures were characterized to be true local energy minima on the potential-energy surface without imaginary frequencies.

The predictions of heats of formation (HOF) of compounds used the hybrid DFT-B3LYP methods with the 6-311++G** basis set through designed isodesmic reactions. The isodesmic reaction processes, that is, the number of each kind of formal bond is conserved, were used with the application of the bond separation reaction (BSR) rules. The molecule was broken down into a set of two heavy-atom molecules containing the same component bonds. The solid phase of heat of formation can be calculated according to the equation 1.

$$\Delta H_{solid} = \Delta H_{gas} - \Delta H_{sub} \tag{1}$$

Here, the heat of sublimation (ΔH_{sub}) was calculated by using an equation (2) proposed by Edward F. C. Byrd, et al.

$$\Delta H_{sub} = aA^2 + b(v\sigma_{tot}^2)^{1/2} + c$$
⁽²⁾

For all the ionic salts, calculation of the HOFs was simplified by using equation (3)

$\Delta_{f}H(ionic \ salts, \ 298K) = \Sigma \Delta_{f}H(cation, \ 298K) + \Sigma \Delta_{f}H(anion, \ 298K) - \Delta H_{L}$ (3)

In eq 3, ΔH_L is the lattice energy of the ionic salts, which could be predicted by using the equation (4) suggested by by Jenkins et al.⁵

$$\Delta H_L = U_{POT} + [p(n_M/2 - 2) + q(n_x/2 - 2)]RT \quad (4)$$

In eq 4, n_M and n_X depended on the nature of ions M_p^+ and X_q^- , respectively, and are equal to 3 for monatomic ions, 5 for linear polyatomic ions, and 6 for nonlinear polyatomic ions.

The lattice-potential energy (U_{POT}) was calculated according to equation (5), in which ρ_m is the density (in g/cm³) and M_m is the chemical formula mass of the ionic material; the coefficients γ and δ were taken from the literature.⁸

$$U_{\rm POT} \,({\rm kJ/mol}) = \gamma \,(\rho_{\rm m}/{\rm M_m})^{1/3} - \delta$$
 (5)
