## 1 Materials and methods

The syntheses were carried out under inert atmosphere in ethanol (99.8%, Carlo Erba). Phthalaldehyde (99%) and 2-hydrazinopyridine (99%) were purchased from Flurochem, and used without further purification. Hydrazinopyridine is susceptible to moisture and after prolong contact with air turns to orange oil, affecting the synthesis outcome. Copper(II) nitrate trihydrate was purchased from Sigma Aldrich at a purity of 99%. Methanol (99.8%, Carlo Erba) was used as solvent for functionalisation. Triethylamine (99.9%) was also used as received from the manufacturer (Sigma Aldrich). Thermally reduced graphene oxide was obtained by Hummer’s method [2] and further thermally reduced in presence of hydrazine (Elemental analysis found: N (%): 0.54; C (%): 85.81; H (%): 1.47; S (%): 0.36)) and graphite was milled (Elemental analysis found: N (%): 0.70; C (%): 97.41; H (%): 0.84; S (%):-).

### 1.1 Preparation of complex 1

Phthalaldehyde (66 mg, 0.50 mmol) and 2-hydrazinopyridine (109 mg, 1.00 mmol) were dispersed in 5 mL of ethanol (99.8%) under Ar atmosphere. The dispersion was heated at 75 °C for 10 min until full dissolution of the reagents. Thereafter, copper(II) nitrate trihydrate (120 mg, 0.496 mmol) was added and mixed until full dissolution. After few minutes of thermostating the reaction mixture at 75 °C the red crystalline product appeared. The mixture was decanted and precipitate was washed with 3 mL portion of ethanol (99.8%). The crystalline product (130 mg, 27.9%) was then dried in air at 75 °C. Elemental analysis calculated for  $\text{C}_{38}\text{H}_{38}\text{Cu}_2\text{N}_{14}\text{O}_7$ : C, 49.08%; H, 4.12%; N, 21.09%; S, -%. Found: C,48.1%; H,4.41%; N, 20.43%; S, -%.  $^1\text{H}$  NMR (500 MHz,  $d_6$ -DMSO):  $\delta$  1.04-1.08 (7H, 1.06 (t, J = 6.99 Hz), 1.06 (t, J = 7.02 Hz)), 2.51 (22H, quint, J = 2.10 Hz), 3.33 (9H, s), 3.45 (4H, m), 7.05 (14H, m), 7.67 (4H, dd, J = 5.54, 3.47 Hz), 7.91 (5H, m), 7.98 (4H, s), 8.11 (5H, d, J = 6.75 Hz), 12.19 (1H, m), 12.17 (4H, s).  $^{13}\text{C}$  NMR (126 MHz,  $d_6$ -DMSO):  $\delta$  56.50, 19.04, 109.28, 153.52, 146.58, 139.75, 138.97, 132.46, 129.19, 126.16, 117.53. HR-MS: m/z calcd for  $\text{C}_{36}\text{H}_{32}\text{Cu}_2\text{N}_{12}$ : 379.072694[M] $^{2+}$ ; 757.14649 [M] $^+$ ; found: 379.07312 [M] $^{2+}$ ; 757.13821 [M] $^+$ . ATR FTIR ( $\text{cm}^{-1}$ ): 3347br, 3213w, 2930br, 1617vs, 1540s, 1482vs, 1423vs, 1337s, 1281s, 1255vs, 1127s, 1073s, 1044m, 1006m, 763vs, 482m. UV-VIS: DMF,  $\lambda_{max}$  [nm] ( $\epsilon$ , [M $^{-1}\text{cm}^{-1}$ ]) 298 (51175), 352 (50138)

## 1.2 Preparation of TRGO\_Cu2 hybrid composite

TRGO (20.9 mg) and  $[\text{Cu}_2\text{L}_2][\text{NO}_3]_2 \cdot \text{C}_2\text{H}_5\text{OH}$  (5.0 mg) were dispersed in 5 mL of methanol under Ar atmosphere, then 0.1 mL of triethylamine has been added and the dispersion was heated at 75 °C for one week. Then, the solid has been centrifuged at 30065 rcf for 15 min, washed with 1.5 mL of methanol and again centrifuged at 30065 rcf for 15 min. The supernatant has been discarded and the solid dried at 80 °C for 24h. Elemental analysis found: C,80.67%; H,1.69%; N, 2.75%; S, 0.31%.

## 1.3 Preparation of graphite\_Cu2 hybrid composite

Graphite (20.9 mg) and  $[\text{Cu}_2\text{L}_2][\text{NO}_3]_2 \cdot \text{C}_2\text{H}_5\text{OH}$  (5.5 mg) were dispersed in 5 mL of methanol under Ar atmosphere, then 0.1 mL of triethylamine has been added and the dispersion was heated at 75 °C for one week. Then, the solid has been centrifuged at 30065 rcf for 15 min, washed with 1.5 mL of methanol and again centrifuged at 30065 rcf for 15 min. The supernatant has been discarded and the solid dried at 80 °C for 24h. Elemental analysis found: C,94.86%; H,0.81%; N, 1.22%; S, -%.

## 1.4 Preparation of single crystals of complex 2

Phthalaldehyde (33 mg, 0.25 mmol) and 0.916 mL of isopropanolic solution of 2-hydrazinopyridine (68 mg/mL) were mixed and heated in a capped 8 mL vial at 75 °C until full dissolution of reagents. Thereafter, ammonium fluoride (56 mg, 1.5 mmol) was added together with copper(II) nitrate trihydrate (49 mg, 0.20 mmol) and 10  $\mu\text{L}$  of pyridine. The red-brown solution was thermostated at 75 °C for two days. The block crystals were dark brown colored and occur in presence of crystals of complex 1. Therefore, the compound has been analysed only by SCXRD and FT-IR on single crystal selected from the batch.

## 1.5 Characterisation

Microanalyses on carbon, hydrogen, nitrogen and sulfur were performed using the Elementar vario EL Cube. The accuracy of the method is specified by the manufacturer for the simultaneous analysis of 5 mg of the standard 4-amino-benzene sulfonic acid in the module CHNS to 0.1% abs. for each element. The analysis results include all combustible sulfur, i.e. both organic and inorganic ( $\text{S}^{2-}$ ,  $\text{SO}_4^{2-}$ ), as well as all combustible carbon, i.e. both organic and inorganic ( $\text{CO}_3^{2-}$ ).

### 1.5.1 X-ray crystal structure, data collection

Diffraction intensity data for single crystals of the new compounds were collected on a (supernova) Kap-paCCD (Nonius) diffractometer with graphite-monochromated  $\text{MoK}\alpha$  radiation ( $\lambda = 0.71073 \text{ \AA}$ ). Corrections for Lorentz, polarisation and absorption effects [Nonius, 1997-2000; [5]] were applied. The structure was solved by direct methods using SIR-92 program package[1] and refined using a full-matrix least square procedure on  $F^2$  using SHELXL-97.[6] Anisotropic displacement parameters for all non-hydrogen atoms and isotropic temperature factors for hydrogen atoms were introduced. In the structure, the hydrogen atoms connected to carbon atoms were included in calculated positions from the geometry of molecules, whereas hydrogen atoms of water molecules were included from the difference maps and were refined with isotropic thermal parameters. The figures were made using Mercury.[3] CCDC-1590016 (for 1) and CCDC-2348643 (for 2) include the supplementary crystallographic data for this work. These data can be obtained free of charge from The Cambridge Crystallographic Data Centre via [www.ccdc.cam.ac.uk/structures](http://www.ccdc.cam.ac.uk/structures).

### 1.5.2 XPS

High-resolution XPS was performed with a SPECS spectrometer using an XR 50 MF monochromatic X-ray radiation source (1486.7 eV) and a Phoibos 150 2D CCD hemispherical analyzer and detector. The pressure inside the chamber during the experiments was set to  $4 \times 10^{-9}$  mbar or lower. Wide-scan surveys were obtained at  $E_p=100$  eV, with subsequent high-resolution scans of the desired core lines carried out at  $E_p=20$  eV with an acquisition step of 0.1 eV. The samples were placed on double-sided carbon tape. The binding energy values were referenced to the adventitious carbon peak at 284.8 eV. The Cu2p core level spectra were measured the first, to avoid copper/ligand oxidation in the X-ray beam.

### 1.5.3 Scanning electron microscopy (SEM)/ Energy-dispersive spectroscopy (EDS)

SEM coupled with EDS was employed to perform surface morphology characterization and elemental mapping analysis. Electron microscopy was conducted on Lyra 3 (Tescan).

### 1.5.4 Transmission Electron Microscopy

TEM with a JEOL 2200 FS microscope (Japan) was operated at an accelerating voltage of 200 kV. SAED patterns were obtained under the same conditions. Elemental analysis was conducted (Zeiss LIBRA 200 MC Cs scanning TEM, 200 kV) in high-angle annular dark-field scanning transmission electron microscopy mode, coupled with energy-dispersive X-ray analysis using a detector of Oxford instruments.

### 1.5.5 Raman spectra

Raman spectra were obtained using a Renishaw inVia confocal micro-Raman spectroscope (Renishaw) in backscattering geometry with a CCD detector, 532 nm DPSS laser, and 20x objective.

### 1.5.6 BET analysis

N<sub>2</sub> adsorption isotherms were measured at 77 K using a NOVAtouch series (Quantachrome Instruments, Anton Paar QuantaTec Inc., USA) to determine the BET area and characterize the pore size distribution of materials. The samples were first activated at 80 °C for 24 h, and N<sub>2</sub> was used as the adsorbate.

### 1.5.7 NMR spectroscopy

The NMR spectra were recorded on a 500 MHz instrument. The chemical shifts ( $\delta$ ) are indicated in ppm followed by integral intensity, multiplicity, corresponding coupling constants (J) in Hz. The <sup>1</sup>H and <sup>13</sup>C chemical shifts are referenced to a residual solvent signal (DMSO-d<sub>6</sub>: 2.50 ppm for <sup>1</sup>H, 39.52 ppm for <sup>13</sup>C).

### 1.5.8 PXRD

XRD tests were carried out using a Bruker D8 Advance. The XRD patterns were obtained at 2-theta from 5° to 50° with a step of 0.02 degree and a integration time of 0.5 seconds.

### 1.5.9 DFT calculations

All the calculations presented in this article were performed with DFT methods using ORCA (version 5.0.0) software.[4] The B3LYP LANL2DZ level of theory was applied in all calculations.

### 1.5.10 ATR-FTIR spectroscopy

The IR spectra were recorded on a Thermo Scientific Nicolet iS5 FT-IR spectrometer equipped with an iD5 diamond ATR attachment. Advanced ATR correction was applied and the spectra were baseline corrected.

### 1.5.11 UV-VIS spectroscopy

The measurements of absorption spectra were performed at PerkinElmer LAMBDA 850+ UV/Vis Spectrophotometer (Shelton, CT, USA) in quartz cuvettes (10.00 mm optical path). The spectra were baseline corrected with the use of pure solvents: methanol, acetonitrile, N,N'-dimethylformamide and chloroform.

### 1.5.12 Electrochemical Impedance Spectroscopy

Impedance measurements were carried out at room temperature (in a vessel of 20 mL containing 2 mL of a given solvent) using an Autolab PGSTAT 204/FRA 32M potentiostat/galvanostat (Eco Chemie, Utrecht, The Netherlands) controlled by NOVA version 2.1 software (Eco Chemie). A sinusoidal potential modulation of 10 mV in amplitude in the 100 Hz to 100 kHz frequency range with a logarithmic scale of 10 points per decade was used. Interdigitated gold electrodes (5/5  $\mu$ m, electrode/gap) produced by Micrux technologies

(Asturias, Spain) were used (ED-IDE3-Au) with the 2-electrode adapter matching the gas containing vessel. The interdigitated electrodes were washed in ethanol aided by sonication (30 min) and dried in a flow of Ar. Then the impedance spectra were collected for air atmosphere and in saturated atmospheres of different solvents. After the initial measurements, the surface of the interdigitated electrode was drop casted (3  $\mu\text{L}$ ) with suspensions of the hybrid composites (graphite-Cu<sub>2</sub> and TRGO-Cu<sub>2</sub>) in dichloromethane (0.25 mg/mL), thereafter the electrodes were allowed to dry in air. The EIS of such electrodes were collected in vapours of different solvents.

## 1.6 Calculation of grain size from PXRD pattern for graphite\_Cu<sub>2</sub> hybrid composite

Given:

$$\beta_{\text{FWHM}} = 0.29466 \text{ degrees } 2\theta$$

$$\lambda = 1.54 \text{ \AA} \text{ngstr\AA} \text{ms}$$

$$\theta = 27.21021 \text{ degrees}$$

The calculation will involve dividing the Bragg angle ( $\theta$ ) by 2 before converting it to radians. Then the Scherrer equation can be used:

Convert the Bragg angle ( $\theta$ ) from degrees to radians:

$$\theta_{\text{rad}} = \frac{\pi \cdot \theta}{180 \cdot 2}$$

$$\theta_{\text{rad}} = \frac{\pi \cdot 27.21021}{180 \cdot 2}$$

$$\theta_{\text{rad}} = 0.23725 \text{ radians}$$

The grain size can be calculated from the Scherrer equation:

$$D = \frac{K \cdot \lambda}{\beta_{\text{rad}} \cdot \cos(\theta_{\text{rad}})}$$

$$D = \frac{0.9 \cdot 1.54}{0.00513 \cdot \cos(0.23725)}$$

$$D = \frac{1.386}{0.00513 \cdot 0.972}$$

$$D = \frac{1.386}{0.004986}$$

$$D \approx 277.94 \text{ \AA}$$

The calculated grain size using the Scherrer equation is approximately 277.94  $\text{\AA}$ .

For the graphite-Cu<sub>2</sub> composite, given:

$$FWHM = 0.1834 \text{ deg}$$

$$\lambda = 1.54184 \text{ \AA}$$

$$\theta = 26.96612 \text{ deg}$$

The Bragg angle  $\theta$  must be converted from degrees to radians:

$$\theta_{\text{rad}} = \frac{\pi \times \theta}{180} = \frac{\pi \times 26.96612}{180} = 0.23518 \text{ rad}$$

The grain size can be calculated:

$$D = K \times \lambda / (FWHM_{\text{rad}} \times \cos(\theta_{\text{rad}}))$$

Substituting  $K = 0.9$ :

$$D = 0.9 \times 1.54184 / (0.1834 \times \cos(0.23518)) = 1.387656 / 0.003183 \times \cos(0.23518) \approx 448.63 \text{ \AA}$$
