## Chemical Reagents

Nickel sulfate hexahydrate ( $\text{NiSO}_4 \cdot 6\text{H}_2\text{O}$ , AR, Aladdin), nickel chloride hexahydrate ( $\text{NiCl}_2 \cdot 6\text{H}_2\text{O}$ ,  $\geq 98.0\%$ , Aladdin), ammonium chloride ( $\text{NH}_4\text{Cl}$ , 99.5%, Aladdin),  $\text{CoSO}_4 \cdot 7\text{H}_2\text{O}$  ( $\geq 99.0\%$ , Aladdin),  $\text{NaH}_2\text{PO}_4 \cdot \text{H}_2\text{O}$  (AR, Aladdin),  $\text{C}_6\text{H}_5\text{Na}_3\text{O}_7 \cdot 2\text{H}_2\text{O}$  (AR, Aladdin), sodium hydroxide (NaOH, AR, Aladdin), potassium hydroxide (KOH,  $\geq 85\%$ , Aladdin), lithium hydroxide monohydrate ( $\text{LiOH} \cdot \text{H}_2\text{O}$ , 98%, Aladdin), boric acid ( $\text{H}_3\text{BO}_3$ ,  $\geq 99.5\%$ , Aladdin), sulfuric acid ( $\text{H}_2\text{SO}_4$ , ACS reagent, 95.0-98.0 %), all the chemicals were of analytical grade and used without further purification.

Indium tin oxide (ITO) was purchased from South China Xiang Cheng Technology Co., Ltd. The photoresist (PR, RZJ-390PG-50CP) was obtained from Suzhou Rui Hong Electronic Chemical Co., Ltd. Deionized water used in all experiments was prepared using a Hitech-K flow water purification system (Hitech Instrument Co., Ltd., Shanghai, China).

## Experimental methods

### Fabrication of 3D Ni Mesh (NM)

A layer of photoresist was first spin-coated onto the indium tin oxide (ITO) substrate at sequential spin speeds of 500 rpm for 10 s and 800 rpm for 30 s. The ITO substrates were then dried at 100°C for 3 minutes. Using a 3D honeycomb-patterned mask plate (7.5  $\mu\text{m}$ , 100  $\times$  100 mm) and exposed to a specific UV wavelength, the photoresist underwent a photochemical reaction, resulting in areas with different solubility. Unexposed photoresist was removed using 0.5% NaOH, yielding precise lithographic patterns. To create an ordered cellular array network, micro-gullies were filled by selective electrodeposition of Ni foam at 2 V and 30 mA  $\text{cm}^{-2}$  for 2400 s. The bath solution composed 7.85 mg  $\text{NiSO}_4 \cdot 6\text{H}_2\text{O}$  and 1.3 mg  $\text{NH}_4\text{Cl}$ . The Ni micromesh (NM) was then peeled off from the ITO by immersing in an etching solution containing 5% NaOH for 1 minute. The resulting 3D Ni mesh had a thickness of approximately 0.004 mm, as shown in Figure S1a.

### Preparation of 3D NM@NiCoP electrode

In the secondary electrodeposition process, a self-supporting 3D NM (1 $\times$ 1  $\text{cm}^2$ ) was immersed in a solution containing 20 mg  $\text{NiCl}_2 \cdot 6\text{H}_2\text{O}$ , 4 mg  $\text{NH}_4\text{Cl}$  and 10 mg  $\text{H}_3\text{BO}_3$  in 100 ml of deionized water (DI). The bath temperature was maintained at 60 °C, and a current density of 10 mA  $\text{cm}^{-2}$  was applied for 600 seconds. NiCoP was electrodeposited onto the 3D Ni mesh to obtain 3D NM@NiCoP. The electrochemical deposition was performed in a standard three-electrode cell (CHI660E), with the 3D Ni mesh as the working electrode, platinum as the counter electrode, and Hg/HgO as the reference electrode. Cycling voltammetry (CV) was conducted with the potential range from -0.3V to -1.2 V at a scan rate of 2 mV  $\text{s}^{-1}$  for 60 cycles. The solution comprised 0.3 mg  $\text{NiSO}_4 \cdot 6\text{H}_2\text{O}$ , 0.3514 mg  $\text{CoSO}_4 \cdot 7\text{H}_2\text{O}$ , 2.6 mg  $\text{NaH}_2\text{PO}_4 \cdot \text{H}_2\text{O}$  and 1.47 mg  $\text{C}_6\text{H}_5\text{Na}_3\text{O}_7 \cdot 2\text{H}_2\text{O}$  in 50 ml DI water.

### Preparation of Zn@Al<sub>2</sub>O<sub>3</sub>@TiO<sub>2</sub> anode

Zinc foil (Zn, 99.9%, 5 $\times$ 5cm) was ultrasonically cleaned in ethanol and DI water to remove surface impurities and then dried at 60°C in vacuum oven for 45 minutes. Using the NCE-200 R atomic layer deposition system, a 10 nm layer of Al<sub>2</sub>O<sub>3</sub> was coated onto the prepared Zn plate at 130°C, followed by the deposition of a 20 nm layer of TiO<sub>2</sub> at 120°C on the Zn@Al<sub>2</sub>O<sub>3</sub>.

### Material characterization and Electrochemical Measurements

Microstructure analysis of the samples was conducted using field-emission scanning electron microscopy (SEM) (Carl Zeiss SIGMA HD) and optical microscopy (Carl-Zeiss AXIO-10). Raman spectra were obtained using a confocal microscopy system with a 532 nm laser wavelength (WITec Alpha-300 R) at room temperature. X-ray diffraction (XRD) patterns were acquired using an Siemens D-5000 diffractometer. Electrochemical depositions were carried out using an electrochemical workstation (CHI660e) and a source meter. All electrochemical measurements, including cyclic voltammetry (CV), galvanostatic charge-discharge (GCD) and electrochemical impedance spectroscopy (EIS), were conducted in a 2 M KOH solution at room temperature using the same electrochemical workstation. In these experiments, the synthesized samples served as the working electrode, while a Pt sheet, and a mercuric oxide electrode (HgO) were used as the counter electrode and the reference electrode, respectively. The charge storage properties of the asymmetric device, constructed with the Zn@AL<sub>2</sub>O<sub>3</sub>@TiO<sub>2</sub> anode and the 3D NM@NiCoP cathode, were evaluated under a two-electrode mode using the electrochemical station.

The areal capacity was calculated according to the following equation:

$$C_a = I \times \Delta t \div (S \times 3.6) \quad (1)$$

Where  $C_a$  ( $\mu\text{Ah cm}^{-2}$ ) represents the areal capacitance,  $I$  (mA) is the charge/discharge current,  $\Delta t$  (s) is the discharge time, and  $S$  is the loading area of the active material ( $1 \times 1 \text{ cm}^2$  in this work).
