## X-ray crystallography and physical measurement

Intensity data for crystals of $\mathbf{1}$ and $\mathbf{2}$ were collected on a rigaku SuperNova, Dual, AtlasS2 diffractometer with graphite-monochromated $\mathrm{Mo} \mathrm{K} \alpha(\lambda=0.71073 \AA)$ radiation at 100 K . Using Olex2, the structure was solved with the olex 2 .solve structure solution program using Charge Flipping and refined with the olex2.refine refinement package using Gauss-Newton minimisation. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were placed at the calculation positions. The details of crystallographic data and selected bond parameters for compounds $\mathbf{1}$ and $\mathbf{2}$ are listed in Table S $1 \uparrow$, Table S $2 \dagger$ and Table S3 $\dagger$, respectively. CCDC 2243064-2243065 contain the supplementary crystallographic data for this paper.

The Fourier transform infrared (FT-IR) spectra were recorded using KBr pellets in the range of 4000 to $400 \mathrm{~cm}^{-1}$ on an AVATAR 360 Nicolet 380 FT/IR spectrometer. Elemental analyses (C, H, N) were implemented on an Elementar Vario EL analyzer.

Powder X-ray diffraction (PXRD) analyses were performed on a Rigaku Dmax-2000 X-ray diffractometer with $\mathrm{Cu} \mathrm{K} \alpha(\lambda=1.54059 \AA)$ radiation. Variable-temperature magnetic susceptibility measurements of $\mathbf{1}$ and $\mathbf{2}$ were performed on Quantum Design PPMS magnetometer ( $100 \sim 10000 \mathrm{~Hz}$ ) and Quantum Design SQUID-MPMS3 (1~1000 Hz ) magnetometer. Prior to magnetic experiment, the crystal sample was encapsulated with film and fixed in an antimagnetic capsule and then placed in a sample holder for testing.

## Computational details

Ab initio calculations on the $\mathrm{Dy}^{3+}$ ion fragment of compound $\mathbf{1}$ and $\mathbf{2}$ on the basis of X-ray determined geometry have been carried out with MOLCAS $8^{1}$ program package. Since the two $\mathrm{Dy}^{3+}$ ions of the dimer units are structurally identical, only calculation based on one of the $\mathrm{Dy}^{3+}$ ions were conducted. The method is to retain one $\mathrm{Dy}^{3+}$ ion while replacing the other with a diamagnetic $\mathrm{Lu}^{3+}$ ion without further optimization.

The basis sets for all atoms are atomic natural orbitals from the MOLCAS ANORCC library: ANO-RCC-VTZP for $\mathrm{Dy}^{3+}$ ion; VTZ for close O and N ; VDZ for distant atoms. The calculations employed the second order Douglas-Kroll-Hess Hamiltonian, where scalar relativistic contractions were taken into account in the basis set and the spin-orbit coupling were handled separately in the restricted active space state interaction (RASSI-SO) procedure. For the fragment of $\mathrm{Dy}^{3+}$ ion, the active electrons in 7 active spaces include all felectrons CAS $(9,7)$ for Compound $\mathbf{1}$ and $\mathbf{2}$ in the CASSCF calculation. To exclude all the doubts, we calculated all the roots in the active space. We have mixed the maximum number of spin-free state which was possible with our hardware (all from 21 sextets, 128 from 224 quadruplets and 130 from 490 doublets for $\mathrm{Dy}^{3+}$ ion fragments).

Fitting the exchange interaction in two compounds using Lines model based on ab

## initio results

With the corresponding calculated results of the mononuclear fragments, the magnetic interactions were further explored. The exchange interaction $J_{\text {exch }}$ between the magnetic centers is considered within the Lines model, while the account of the dipole-
dipole magnetic coupling $J_{\text {dip }}$ is treated exactly. The $J_{\text {exch }}$ could be described with Hamiltonian S1 shown below. The Lines model is effective and has been successfully used widely in the research field of f-element single-molecule magnets.

$$
\begin{align*}
& )_{\text {exch }}=-J_{\text {exch }} \hat{S} / g_{y 1} \hat{S} / g_{y 1 A}  \tag{S1}\\
& J_{\text {dip }}=\frac{\mu_{0} \mu_{B}^{2}}{4 \pi|r|^{2}} g_{1 z} g_{2 z}\left(1-3 \cos ^{2} \theta\right)  \tag{S2}\\
& J_{\text {total }}=J_{\text {dip }}+J_{\text {exch }} \tag{S3}
\end{align*}
$$

The ${ }^{\hat{S} / 8 y}= \pm 1 / 2$ are the ground pseudospin on the $\mathrm{Dy}{ }^{3+}$ ion sites. The $J_{\text {dip }}$ parameters can be calculated exactly on account of the X-ray determined molecular structures using the eqn (S2), where $|r|$ was the distance between two $\mathrm{Dy}^{3+}$ ions and $\theta$ was the angle between the $r$ vector and magnetic easy axis. The $J_{\text {exch }}$ was fitted through comparison of the computed and measured magnetic susceptibility and molar magnetization using the POLY_ANISO program. ${ }^{2}$
