1. Supplementary Experiments

1.1 Characterization

X-ray diffraction (XRD) patterns of the catalysts were measured on an X-ray diffractometer (XRD, DX-2700) with monochromatized Cu Kα radiation (λ = 1.5406 Å). Scanning electron microscopy (SEM) imaging was performed on a ZEISS Ultra-55 field-emission scanning electron microscope at an acceleration voltage of 3 kV. Transmission electron microscopy (TEM) imaging and energy dispersive X-ray (EDX) element mapping were performed on a JEOL-2100 transmission electron microscope at an acceleration voltage of 200 kV. X-ray photoelectron spectroscopy (XPS) analysis was performed on an X-ray photoelectron spectrometer (Thermo Fisher Scientific K-Alpha) by using monochromated Al Kα radiation (1486.6 eV) and a high-resolution pass energy of 30 eV with a spot size of 400 μm. The spectra were calibrated according to the C 1s peak of adventitious carbon species at 284.8 eV. The electron spin resonance (ESR) was measured on a Bruker model JEOL JES-FA200 spectrometer. UV-vis-NIR diffused reflectance absorption spectra (DRS) were recorded on a Hitachi UH4150 spectrophotometer. Both CO_2 adsorption (273 K) and N_2 adsorption-desorption isotherms (77 K) were measured on a physisorption apparatus of Micromeritics ASAP 2020. Inductively coupled plasma optical emission spectroscopy (ICP-OES) analysis was conducted on the Agilent 5800 instrument.

1.2 Computational method

Density functional theory (DFT) calculations were carried out using Vienna ab-initio Simulation Package (VASP). The interaction between core and valence electrons was described employing the Projected Augmented Wave (PAW) method. The electron exchange and correlation effects were addressed using the Perdew-Burke-Ernzerhof (PBE) functional form based on the generalized-gradient approximation (GGA). A $2\times2\times1$ Monkhorst-Pack grid of size was employed for the calculations. An energy cutoff of 400 eV for the plane-wave basis was set to ensure the precision. All slab models were applied with 20 Å vacuum layer to avoid the vertical interactions. DFT-D3 method was applied to consider the long-range van der Waals interaction for the adsorption over substrate. The atomic positions were extensively relaxed until the remaining force of each atom is less than 0.05 eV/Å. The binding energy between the adsorbate (ad) and the substrate (sub) is defined by $E_{binding}=E_{ad@Sub}-E_{sub}-E_{ad}$, where $E_{ad@sub}$ is the total energy of substrate with an adsorbed intermediate, E_{sub} and E_{ad} are the energy of substrate and a single adsorbate in vacuum. DFT calculated energies were corrected into free energies (G) according to $G=E_{DFT}+E_{ZPE}-TS$ (298.15K). E_{DFT} is the electronic energy of each step, E_{ZPE} is the zero-point energy and S is the entropy. Meanwhile, the proton-coupled electron (H^++e^-) transfer during alkyne reduction was simulated with the computational hydrogen electrode (CHE) model. The transition states were searched by means of the climbing image nudged elastic band (CI-NEB) method by relaxing the remaining force below 0.05 eV/Å. The barrier energy (E_a) was calculated according to $E_a=E_{TS}-E_{IS}$, where E_{TS} and E_{IS} are the total energy of the corresponding initial state (IS) and transition state (TS), respectively. The optimized

configurations, adsorption energies, and differential charge densities of CO_2 and H_2O on $W_{18}O_{49}$ and $Pd/W_{18}O_{49}$, where the isosurface value was set as 0.0005 e Å^{-3} for CO_2 adsorption and 0.001 e Å^{-3} for H_2O adsorption.

1.3 Electrochemical measurements

Electrochemical tests were performed using a three-electrode system on an electrochemical workstation (CHI660E, China). The catalyst-coated fluorine-tin-oxide (FTO) glass, platinum wire and Ag/AgCl electrode served as the photoelectrode, counter electrode, and reference electrode, respectively. The linear sweep voltammetry (LSV) profiles of H_2O oxidation were measured at a scan rate of 10 mV s^{-1} in the Ar-saturated 0.1 M $KHCO_3$ aqueous solution, and the applied bias voltage was set in the range of 0 – 2.3 V (vs. Ag/AgCl). The LSV profiles of CO_2 reduction were measured at a scan rate of 10 mV s^{-1} in the CO_2-saturated 0.1 M $KHCO_3$ aqueous solution, with the applied bias voltage ranging from –2.3 to 0 V (vs. Ag/AgCl). The Mott-Schottky plots were recorded at the frequencies of 500, 1000, and 1500 Hz, respectively, with the potential ranging from -2.0 to 2.0 V. The tests were conducted in a 0.1 M Na_2SO_4 solution electrolyte, using a three-electrode system.

1.4 Detection of H_2O_2 generated in photocatalytic CO_2 reduction system

Hydrogen peroxide (H_2O_2) generated in the photocatalytic CO_2 reduction process was analyzed by an iodimetry method. After the photocatalytic reaction, the catalyst was dispersed into 2 mL of deionized water, followed by centrifugation and filtration through a syringe filter. The filtrate was added into a mixture of potassium hydrogen phthalate ($C_8H_5KO_4$) aqueous solution (1 mL, 0.1 M) and potassium iodide (KI)

aqueous solution (1 mL, 0.4 M), where H_2O_2 could react with I^- ions to produce I^{3-} that

has a characteristic absorption peak at 350 nm. The UV-vis absorption spectra of the

solution were recorded in the wavelength range of 300-500 nm by a Shimadzu UV-2600

spectrophotometer, to quantify the generated H_2O_2.

Fig. S23. (a) Tauc plot, and (b) Mott-Schottky plots of the $Pd/W_{18}O_{49}$ catalyst.

The optical bandgap of $W_{18}O_{49}$ in the catalyst can be determined as 2.63 eV. The positive slopes of Mott-Schottky plots indicate that $W_{18}O_{49}$ is an n-type semiconductor. The transverse intercept value of -0.20 V (vs Ag/AgCl, pH = 7) corresponds to the flat-band potential of $W_{18}O_{49}$ in the catalyst, which can be converted to the normal hydrogen electrode (NHE) scale using the following equation: $E_{(NHE)} = E_{(Ag/AgCl)} + 0.197$ V.[1] It is generally considered that the conduction band (CB) position of an n-type

semiconductor is approximately $0.1-0.3$ eV below the flat band potential.[1-3] As a result, the CB position is approximate to -0.3 V (vs. NHE), and the VB position is estimated to be 2.33 V (vs. NHE) according to the relationship of $E_g = E_{VBM} - E_{CBM}$.

3. Supplementary Tables

Table S1. BET surface areas and pore size distributions of $W_{18}O_{49}$ and $Pd/W_{18}O_{49}$.

Sample	BET surface area (m²/g)	Pore volume (cm³/g)	Average pore size (nm)
$W_{18}O_{49}$	141.694	0.161	4.552
$Pd/W_{18}O_{49}$	126.612	0.135	4.261

Table S2. Atomic proportions of different O and W species from the deconvolution of O 1s and W 4f XPS spectra of the pristine samples.

Sample	O_{lat}	O_{def}	W^{6+}	W^{5+}	W^{4+}
$W_{18}O_{49}$	86.24	13.76	39.28	47.03	13.69
$Pd/W_{18}O_{49}$	92.43	7.57	50.21	40.87	8.92

Table S3. Results of photocatalytic CO_2 reduction reactions under UV-vis illumination in the presence of $W_{18}O_{49}$ and $x\%Pd/W_{18}O_{49}$ catalysts before and after the preactivation, respectively.

Catalyst	State	CH$_4$ yield (μmol g$_{cat}^{-1}$ h^{-1})	CO yield (μmol g$_{cat}^{-1}$ h^{-1})	CH$_4$ yield selectivity (%)
$W_{18}O_{49}$	Pristine	0.57	0.32	64.0
	Preactivated	1.18	0.47	71.5
$0.3\%Pd/W_{18}O_{49}$	Pristine	1.78	1.33	57.2
	Preactivated	3.28	1.02	76.3
$0.5\%Pd/W_{18}O_{49}$	Pristine	3.26	2.18	59.9
	Preactivated	10.83	1.13	90.6
$0.8\%Pd/W_{18}O_{49}$	Pristine	4.39	3.51	55.6
	Preactivated	**12.22**	**1.55**	**88.7**
$1.0\%Pd/W_{18}O_{49}$	Pristine	2.62	2.15	54.9
	Preactivated	4.72	1.80	72.4

Table S4. Results of photocatalytic CO_2 reduction reactions under different illuminations in the presence of preactivated $Pd/W_{18}O_{49}$ catalyst.

Entry	Light	Temperature (°C)	CH_4 ($\mu mol\ g_{cat}^{-1}\ h^{-1}$)	CO ($\mu mol\ g_{cat}^{-1}\ h^{-1}$)	CH_4 selectivity (%)
1	UV-vis-NIR	202.7	27.27	1.72	94.1
2	UV-vis	59.9	12.22	1.55	88.7
3	Vis-NIR	180.2	7.28	1.13	86.6
4	Vis	55.0	3.40	0.84	80.2
5	NIR	110.0	3.18	0.89	78.1

Table S5. Cyclic tests of photocatalytic CO_2 reduction on the preactivated $Pd/W_{18}O_{49}$ catalyst under UV-vis-NIR illumination, 5 h for each cycle.

Cycle times	CH_4 ($\mu mol\ g_{cat}^{-1}\ h^{-1}$)	CO ($\mu mol\ g_{cat}^{-1}\ h^{-1}$)
1	27.31	1.48
2	26.51	1.43
3	25.51	1.52
4	26.11	1.67

Table S6. The comparison of photocatalytic CO_2 conversion performance between the present Pd/$W_{18}O_{49}$ catalyst and the previously reported $W_{18}O_{49}$-based catalysts.

Catalyst	Reaction system	Photosensitizer & sacrificial agent	Yield rate ($\mu mol\ h^{-1}\ g^{-1}$)	Ref.
Pd/$W_{18}O_{49}$	H_2O vapor + CO_2 gas	/	CH$_4$: 27.27 CO: 1.72	This work
$W_{18}O_{49}$	H_2O + CO_2	/	CH$_4$: 2.2	4
Cu-$W_{18}O_{49}$	H_2O vapor + CO_2 gas	/	CH$_4$: 0.67	5
$W_{18}O_{49}$@Co	gas-liquid system	[Ru(bpy)$_3$]Cl$_2$·6H$_2$O TEOA	CO: 21.18 H$_2$: 6.49	2
Ni$_1$/WO$_{2.72}$	gas-liquid system	[Ru(bpy)$_3$]Cl$_2$·6H$_2$O TEOA	CO: 80.5	3
Au/TiO$_2$/$W_{18}O_{49}$	H_2O vapor + CO_2 gas	/	CH$_4$: 35.55 CO: 2.57	6
$W_{18}O_{49}$/Cu$_2$O	H_2O vapor + CO_2 gas	/	CH$_4$: 17.2	7
SiC-$W_{18}O_{49}$	H_2O vapor + CO_2 gas	/	CH$_4$: 6.62 CO: 11.96 CH$_3$OH: 3.29	8
C-In$_2$O$_3$/$W_{18}O_{49}$	H_2O+NaHCO$_3$+H$_2$SO$_4$	/	CO: 135.82	9
