## Experimental Section

### Chemicals

Chromic(III) chloride hexahydrate ( $\text{CrCl}_3 \cdot 6\text{H}_2\text{O}$ , AR), iron(III) chloride hexahydrate ( $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$ , AR), cobalt chloride hexahydrate ( $\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$ , AR), nickel(II) chloride hexahydrate ( $\text{NiCl}_2 \cdot 6\text{H}_2\text{O}$ , AR), manganese(II) chloride tetrahydrate ( $\text{MnCl}_2 \cdot 4\text{H}_2\text{O}$ , AR) and magnesium chloride hexahydrate ( $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$ , AR) were purchased from Aladdin. Zinc chloride ( $\text{ZnCl}_2$ ,  $\geq 98\%$ ) was purchased from Alfa Aesar. Dicyanamide ( $\text{C}_2\text{H}_4\text{N}_4$ , AR) and ammonium chloride ( $\text{NH}_4\text{Cl}$ , AR) were purchased from Sinopharm Chemical Reagent Co. Ltd. Potassium hydroxide ( $\text{KOH}$ ,  $\geq 85\%$ ) and ethanol ( $\text{C}_2\text{H}_5\text{OH}$ , 99.99%) were purchased from Shanghai Fuchen Chemical Reagent Co., LTD. Nafion 117 solution (5 %) was purchased from Sigma-Aldrich. Ultrapure water with a resistivity of 18.2  $\text{M}\Omega \text{ cm}$  made from a Milli-Q water purification system was used in this work. Unless otherwise noted, all solvents and pharmaceuticals are commercially available and can be used directly.

### Preparation of high-entropy catalysts

The  $(\text{FeCoNiCrZn})_3\text{O}_4$  HESO was synthesized by low temperature template sintering method. Firstly,  $(\text{FeCoNiCrZn})\text{O-CN}$  nanosheet was prepared. In detail, 5 g  $\text{NH}_4\text{Cl}$  and 1 g  $\text{C}_2\text{H}_4\text{N}_4$  were dissolved in 20 mL deionized water at 50 °C under sustained stirring and cooled down to room temperature (named as solution A). In addition, the equimolar  $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$ ,  $\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$ ,  $\text{NiCl}_2 \cdot 6\text{H}_2\text{O}$ ,  $\text{CrCl}_3 \cdot 6\text{H}_2\text{O}$  and  $\text{ZnCl}_2$  (total metal salts of 0.91 mmol) and 16.7 g  $\text{NH}_4\text{Cl}$  was dissolved in 100 mL deionized water under continuously stirring (named as solution B). Then, 10 mL of solution B was mixed with 20 mL of solution A. Following that, the mixed solution was vigorously stirred for 30 minutes to obtain a homogeneous solution at room temperature, and named as solution C. The solution C was exposed to freeze-drying in a freeze dryer with a vacuum for 48 h. Finally, the freeze-dried powder was placed in a covered crucible under air and heated at 550 °C for 4 h with a heating rate of 3 °C /min in a muffle furnace to obtain  $(\text{FeCoNiCrZn})\text{O-CN}$  nanosheet.

The  $(\text{FeCoNiCrZn})_3\text{O}_4$  HESO nanosheet was synthesized from the precursor of  $(\text{FeCoNiCrZn})\text{O-CN}$  nanosheet. Briefly, the resultant  $(\text{FeCoNiCrZn})\text{O-CN}$  was milled into a powder in a mortar. Then, the  $(\text{FeCoNiCrZn})\text{O-CN}$  powder was transferred into a crucible and heated at 550 °C for 1 h at a rate of 3 °C /min in a muffle furnace. As a result, the  $(\text{FeCoNiCrZn})_3\text{O}_4$  HESO nanosheets were obtained. Quaternary metal oxide  $(\text{FeCoNiCr})_3\text{O}_4$  and quinary metal oxides  $((\text{FeCoNiCrM})_3\text{O}_4$ , where M is Mn or Mg) were prepared using the same method using the corresponding as-synthesized metal hydrochloride templates.

### **Characterizations of materials**

The morphology of the samples was characterized by transmission electron microscopy (TEM) microscope with a LaB6 Gun (Tecnai G2 Spirit TWIN, FEI, America) and the microstructure and element mapping of the samples were characterized by Tecnai G2 F20 High-resolution transmission electron microscopy (HRTEM) produced by FEI Company of the United States. The composition of the samples was analyzed using energy dispersive spectroscopy (EDS) equipped in the TEM. The structure of the as-prepared samples was characterized by X-ray diffraction (XRD) (SmartLab 9 KW, Rigaku, Japan) with Cu  $K\alpha$  radiation ( $\lambda = 1.54178 \text{ \AA}$ ). X-ray photoelectron spectra (XPS, ESCALAB 250 Xi spectrometer, Thermo Scientific, America) with an Al  $K\alpha$  as the excitation source was used to investigate the energies of the elements on the surface and the binding energy of C 1s was fixed at 284.8 eV to correct the XPS spectrum.

### **Electrochemical measurements of catalysts for OER**

The electrochemical measurements of as-prepared samples were carried out in a standard three electrode cell system connected to an electrochemical workstation (CHI 760E, Shanghai Chenhua) in 100 mL 1.0 mol/L KOH in the air atmosphere at room temperature (25 °C). A graphite rod was used as the counter electrode, an Ag/AgCl electrode was used as the reference electrode and glassy carbon electrode (GCE) with diameter of 3 mm coated with catalysts was used as working electrode.

The area of the GCE was calculated to be  $0.0707 \text{ cm}^2$ , which was used to determine the current density in the linear scan voltammetry (LSV). Before each measurement, the GC electrode was polished with alumina powder and rinsed thoroughly with deionized water and ethanol to avoid any contamination from previous measurements. For the preparation of the working electrode, 3 mg catalyst was ultrasonically dispersed into a solution consisting of 960  $\mu\text{L}$  of ethanol, 2 mg carbon power (Vulcan XC 72) and 40  $\mu\text{L}$  of Nafion solution (5 wt%). 10  $\mu\text{L}$  of the formed catalyst slurry dropped onto the GC electrode and allowed to dry naturally under ambient conditions. The mass loading was  $0.85 \text{ mg/cm}^2$ .

Before OER measurements, 20 cycles of cyclic voltammetry activation were conducted in a potential range from 1.2 to 1.8 V versus RHE at a scan rate of 100 mV/s to obtain stable polarization curves without iR-compensation. All potentials in this work were calibrated to reversible hydrogen electrode (RHE) according to the Nernst equation:  $E_{\text{RHE}} = E_{\text{Ag/AgCl}} + 0.059 \times \text{pH} + 0.204$ . The Tafel slopes were calculated according to  $\eta = a + b \log j$ , where  $b$ ,  $\eta$ , and  $j$  are attributed to the Tafel slope, overpotential, and current density, respectively. Electrochemical impedance spectroscopy (EIS) is performed at the potential corresponding to  $10 \text{ mA/cm}^2$  within a frequency range of 0.01-1000,000 Hz with a 5 mV AC amplitude. Electrochemical impedance spectroscopy (EIS) was measured at 5 mV from 1000,000 to 0.01 Hz. To determine the ECSAs of the as-prepared catalysts, double layer capacitance ( $C_{\text{dl}}$ ) was determined from the cyclic voltammetry curves recorded at different scan rates (10, 15, 20, 25, and 30 mV/s) in the non-Faradaic potential range of 0.95-1.05 V versus RHE. The  $C_{\text{dl}}$  was obtained by plotting  $\Delta J = (J_{\text{a}} - J_{\text{c}}) / 2$  at 1.0 V versus RHE against the scan rates, where  $J_{\text{a}}$  and  $J_{\text{c}}$  are the anodic and cathodic current densities, respectively. The ECSA was estimated following the equation:  $\text{ECSA} = C_{\text{dl}} / C_{\text{s}}$ , where  $C_{\text{s}}$  is the specific capacitance and is  $40 \mu\text{F/cm}^2$  according to the literature. Faradaic efficiency (FE) is determined using the formula:  $\text{FE} = V_{\text{e}} / V_{\text{t}}$ . The  $V_{\text{e}}$  reflects the experimental volume of the generated  $\text{O}_2$  gas, and  $V_{\text{t}}$  denotes the calculated volume of  $\text{O}_2$  gas, determined by the formula:  $V_{\text{t}} = V_{\text{m}} Q / nF$ , where  $V_{\text{m}}$  (the molar volume of the ideal gas) is defined as  $22.4 \text{ L/mol}$ ,  $Q$  is the electric charge quantity and  $n$  (the number

of electrons transfer) is 4 for OER. The long term stability of the as-prepared catalysts was evaluated by the chronoamperometry method. All electrochemical results are presented without IR compensation.

### **The details of in-situ Raman spectroscopy**

The Raman spectra were taken on a high-resolution laser confocal fiber Raman spectrometer (HORIBA EVOLVTION, HORIBA Jobinyvon, France). The wavelength of the laser excitation source was 532 nm with a power of ~0.5 mW at a grating of 800 mm, and test wavelength 300-1200  $\text{cm}^{-1}$ . Raman signals were recorded in-situ at OCP and under different applied potentials spanning from 1.1 V to 1.5 V vs RHE.

### **The details of in-situ FT-IR spectroscopy**

ATR-SEIRAS was conducted using the ThermoFisher Nicolet iS50. An ultrathin Au layer was chemically deposited on the flat surface of a cylindrical silicon prism. The catalyst ink preparation method was the same as in electrochemical measurements. 100  $\mu\text{L}$  of the catalyst ink solution was loaded on the gold-plated Si prism by drop-cast and dried under ambient conditions. The FTIR tests were conducted in a glassy four-necked electrolysis cell in 1 M KOH. The FTIR spectra were collected in the potential range from OCP to 1.70 V with an interval of 50 mV under OER reaction conditions.
