Experimental

Materials and Methods. All other chemicals were commercially purchased and utilized without undergoing additional purification. The potassium salt of the $K_8[Ta_6O_{19}] \cdot 17H_2O$ and $Na_{10}[A-\alpha-SiW_9O_{34}] \cdot 18H_2O$ precursor was synthesized according to the procedures outlined in the existing literature and its identity was verified through IR spectroscopy.^{1,2} IR spectra of all compounds were obtained using a Bruker VERTEX 70 IR spectrometer with KBr pellets in the range of 4000–500 cm⁻¹. Thermogravimetric analysis (TGA) analyses was conducted using a NETZSCH STA 449 F5 Jupiter thermal analyzer under a flowing N₂ atmosphere with a heating rate of 10 °C min⁻¹. Powder X-ray diffraction (PXRD) data were conducted using an X-ray powder diffractometer (Bruker, D8 Advance) using Cu K α radiation ($\lambda = 1.5418 \text{ \AA}$) collected with the angular range (2θ) from 5° to 45° at room temperature. ICP analyses were achieved on a PerkinElmer Optima 2000 ICP-OES spectrometer. The proton conduction data was collected by impedance phase gain analyzers Solartron 1296.

Syntheses of Li₇KNa₁₁H₆[Si₂Ta₂₄(O₂)₂₀O₅₂(OH)₉]·85H₂O (1). $K_8[Ta_6O_{19}] \cdot 17H_2O$ (2.805 g, 1.397mmol) was dissolved in 150 mL of H₂O. Subsequently, 30 mL 30% H₂O₂ solution was added. This was followed by the sequential addition of 7 mL 1M HCl and 3.345 g $Na_{10}[A-\alpha-SiW_9O_{34}] \cdot 18H_2O$. The suspension was agitated until a yellow clear solution was achieved, and 10 mL 6 M LiCl solution was added finally. The resulting solution was maintained at a temperature of 90 °C in a water bath for 3 h, followed by cooling to room temperature and subsequent filtration. Slow evaporation at room temperature led to the formation of colorless lamellar crystals for compound **1** after approximately one week. (yield: 8.60 % based on $K_8[Ta_6O_{19}] \cdot 17H_2O$). IR (KBr pellets, cm⁻¹): 3402 (br), 1643 (s), 951 (s), 891 (s), 844 (s), 741 (w), 515 (s).

X-ray crystallographic. The appropriate single crystal of compound **1** was affixed to the loop for

data collection at 150 K. Indexing and data collection was performed on a Bruker *D8 VENTURE PHOTON II* diffractometer, employing Mo $K\alpha$ radiation ($\lambda = 0.71073 \text{ \AA}$). Direct methods successfully located the tungsten atoms, and the remaining atoms were revealed through successive Fourier syntheses. Refinements were conducted through full-matrix least-squares on F^2 utilizing the SHELXL-2018 software suite for all the data.³ In the final refinement, all the non-hydrogen atoms except those water O atoms were refined anisotropically. Most lattice water molecules were located by using a Fourier map, and the remaining lattice water molecules were determined by TGA results. All hydrogen atoms on water molecules could not be well located from the electron density map, which were directly included in the molecular formula.

Proton conduction experiments. AC impedance measurements were carried out Solartron Analytical ModuLab 1296 at frequencies ranging from 1 Hz to 10 MHz. The relative humidity was monitored with a STIK Corp CIHI-150BS3 incubator. The samples were pressed into a cylindrical compact of crystalline powder sample (~1 mm thickness \times 3 mm diameter). Two silver electrodes were fastened to both edges of the pellet, forming four end terminals (quasi-four-probe method). Each humidity equilibrium and the thermal equilibrium were preserved for 1 h. The ZsimpWin software was utilized to model the equivalent circuit of the impedance data. The proton conductivity (σ) and activation energy (E_a) were calculated by the following two following equations:

$$\sigma = d/RS \quad (1)$$

$$\sigma T = \sigma_0 \exp(-E_a/k_B T) \quad (2)$$

where d is the thickness (cm) of the slice, S is the electrode area (cm^2), R is the resistance (Ω), σ_0 is the pre-exponential factor, T represents the absolute temperature, and k_B is the Boltzmann constant ($k_B = 8.63 \times 10^{-5} \text{ eV/K}$).

Table S1. Summary of heteropolyoxoniobate.

	Year	Compounds	Ref.
