## 1 **Experimental section**

### 2 ***Materials:***

3 Ytterbium (III) chloride hexahydrate ( $\text{YbCl}_3 \cdot 6\text{H}_2\text{O}$ , 99.99%), yttrium (III) chloride  
4 hexahydrate ( $\text{YCl}_3 \cdot 6\text{H}_2\text{O}$ , 99.99%), indium chloride hydrate ( $\text{InCl}_3 \cdot 6\text{H}_2\text{O}$ , 99.99%),  
5 thulium chloride hexahydrate ( $\text{TmCl}_3 \cdot 6\text{H}_2\text{O}$ , 99.99%), and Zn foils (99.99%) were  
6 obtained from Energy Chemical. Zirconium (IV) chloride ( $\text{ZrCl}_4$ , 99.5%) was bought  
7 from Strem Chemicals, Inc. Zinc sulfate was purchased from Sigma-Aldrich. All  
8 reagents were used directly without further purification. Deionized (DI) water was  
9 thoroughly used during the experiment.

### 10 ***Preparation of CNFs/HEO:***

11 Equivalent stoichiometric amounts of  $\text{YbCl}_3 \cdot 6\text{H}_2\text{O}$ ,  $\text{YCl}_3 \cdot 6\text{H}_2\text{O}$ ,  $\text{InCl}_3 \cdot 6\text{H}_2\text{O}$ ,  
12  $\text{TmCl}_3 \cdot 6\text{H}_2\text{O}$ , and  $\text{ZrCl}_4$  were dissolved in 7 mL DMF in turn. Subsequently, 500 mg  
13 PAN was added, and the mixture was stirred at 50°C for 10 h to make sure the complete  
14 dissolution of each component. Electrospinning was conducted by TEADFS-100  
15 (Beijing Technova Technology Co., Ltd.). The flow rate of the spinning solution was  
16 0.013 mL/min and collected by aluminum foil fixed on a grounded steel drum. The as-  
17 prepared fibers were placed in an oven at 80 °C for 12 h until DMF was completely  
18 removed. The fibers were first stabilized at 220°C for 2 h and then heated to 900°C for  
19 2 h with a heating rate of 2°C/min in an Ar atmosphere. The as-prepared material was  
20 named as CNFs/HEO.

### 21 ***Preparation of CNFs/ $\text{Yb}_2\text{O}_3$ :***

22 1.5 mmol  $\text{YbCl}_3 \cdot 6\text{H}_2\text{O}$  was added to 7 mL DMF with continuous stirring. After

1 complete dissolution, 500 mg PAN was added. The mixed solution was stirred at 50°C  
2 for 10 h. The electrospinning procedure and parameter were identical to the  
3 CNFs/HEO.

#### 4 ***Synthesis of the cathode and battery Assembly:***

5 Firstly, activated carbon were mixed and ground in a mortar with iodine in a mass  
6 ratio of 1:1.2. Then, the mixture was transferred into a glass tube and thermally sealed.  
7 After heating at 120 °C for 6 h, the powder was collected and ground in a mortar with  
8 acetylene black, CMC, and SBR in a mass ratio of 7:2:0.5:0.5. Then, the mixture was  
9 applied to the carbon cloth. The cathode was dried in a vacuum oven at 30 °C for 6 h.  
10 The active material (I<sub>2</sub>) loading of the individual electrode was about 1.0-1.2 mg cm<sup>-2</sup>.  
11 CNFs/Yb<sub>2</sub>O<sub>3</sub> and CNFs/HEO were used as the cathode-modified interface and  
12 assembled between the cathode and the separator. 120 μL of 2 M ZnSO<sub>4</sub> was selected  
13 as an electrolyte.

#### 14 ***Electrochemical measurements:***

15 The electrochemical impedance spectroscopy (EIS) was collected over the frequency  
16 range from 100 kHz to 0.1 Hz. Cyclic voltammetry (CV) was tested on the CHI760E  
17 electrochemical workstation with a voltage range between 0.6 and 1.6 V at a scan rate  
18 of 0.5 mV s<sup>-1</sup>. The discharge-charge cycling of Zn-I<sub>2</sub> was measured on the Neware  
19 battery test system (CT-ZWJ-4'S-T-1U, Shenzhen, China) and LAND battery test  
20 instrument (CT2001A, LAND, China) within a voltage range of 0.6-1.6 V.

#### 21 ***Materials characterization:***

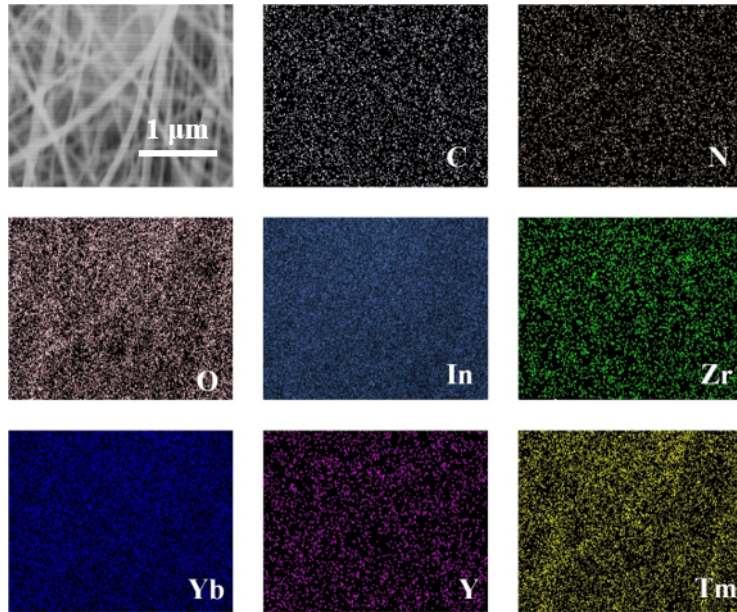

22 X-ray powder diffraction (XRD) analysis was obtained on a D8 Focus diffractometer

1 (Bruker) with Cu-K $\alpha$  radiation ( $\lambda=0.15405$  nm) from Rigaku Corporation in Japan.  
2 High-resolution transmission electron microscope (HR-TEM) characterizations were  
3 taken by JEOLJEM-2100F transmission electron microscope at 200 kV accelerating  
4 voltage. Scanning electron microscopy (SEM) images were measured by HITACHI  
5 SU8010 field-emission scanning electron microscope (FEI Co.) with an energy-  
6 dispersive X-ray spectrum (EDS) from the Hitachi Limited in Japan. Raman spectrum  
7 was recorded at room temperature with a JY HR-800 LabRam confocal Raman  
8 microscope in a backscattering configuration with an excitation wavelength of 488 nm.  
9 X-ray photoelectron spectrum (XPS) was tested on an ECSALAB 250 using non-  
10 monochromatized Al-K $\alpha$  radiation. An atom force microscope (AFM) was performed  
11 on Asylum Research Cypher ES.

## 12 *DFT calculations:*

13 First-principles calculations are performed in the framework of Density Functional  
14 Theory (DFT), which is implemented in the Vienna Ab initio simulation package  
15 (VASP)<sup>1,2</sup>. The projector augmented wave (PAW)<sup>3</sup> potential was used with a plane-  
16 wave cutoff energy of 500 eV. Conjugate gradient method was used for geometric  
17 optimization, with the convergence threshold set at  $10^{-6}$  eV per atom in energy and 0.01  
18 eV $\cdot\text{\AA}^{-1}$  in force. A vacuum distance of  $>15$   $\text{\AA}$  was employed to avoid interactions of  
19 neighboring images. The DFT-D3 method including vdW is used to deal with the inter-  
20 layer van der Waals forces<sup>4</sup>. Considering the strong correlation of transition metals, the  
21 density of states (DOS) was calculated by the GGA+U method<sup>5</sup>.

2 Fig. S6 (a) CV curves at different scan rates, (b) Log (i) -log (v) plots for specific peak  
 3 current, (c) Capacitive contribution at 1.5 mV s<sup>-1</sup>, and (d) Capacitive and diffusion  
 4 contribution versus scan rate curve of CNFs/Yb<sub>2</sub>O<sub>3</sub>.

5 Generally speaking, the peak current (i) and scan rate (v) maintain a functional  
 6 relationship as follows:

$$7 \quad i = av^b \quad (1)$$

8 where a and b represent arbitrary coefficients<sup>6,7</sup>. When the b value is close to 0.5, the  
 9 electrochemical kinetics is denoted by the diffusion process caused by zinc ion (de)-  
 10 intercalation. When b is closer to 1.0, it demonstrates that a surface redox reaction  
 11 dominates the capacitive behavior. While the value of b is between 0.5 and 1.0, it means  
 12 the electrochemical kinetics is determined by both the diffusion process of Zn<sup>2+</sup> and the  
 13 capacitive behavior. Additionally, according to

$$i = k_1v + k_2v^{1/2} \quad (2)$$

the specific contributions of the capacitive behavior ( $k_1v$ ) and the diffusion-controlled insertion ( $k_2v^{1/2}$ ) at different scan rates were calculated<sup>8,9</sup>.

5

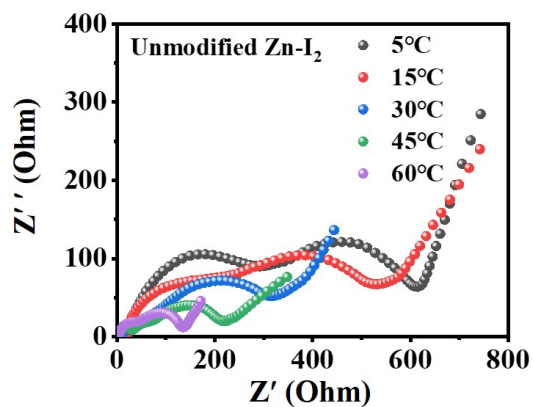

6 Fig. S7 Arrhenius activation energy ( $E_a$ ) of (a) CNFs/HEO and (b) CNFs/Yb<sub>2</sub>O<sub>3</sub>  
7 batteries.

8  $E_a$  of the I<sub>2</sub> reduction process can be calculated according to the following Arrhenius  
9 equation:

$$1/R_{ct} = A \exp(-E_a / RT)$$

11 Where  $R_{ct}$ ,  $A$ ,  $R$ , and  $T$  represent the charge-transfer resistance, frequency factor, gas  
12 constant, and absolute temperature, respectively. EIS profiles of the four electrodes at  
13 different temperatures from 5 to 60 °C were tested.
