Preparation of (*S*)- and (*R*)-MTPA esters of **5**.

The anhydrous CH_2Cl_2 approximately 2 mL was used to dissolve a sample of compound **5** (0.7 mg). Then, dimethylaminopyridine (30 mg) was added to the transparent solution. Subsequently, triethylamine was taken, followed by (*S*)-MTPA chloride (20 μL) to the solution . After mixing, it was reacted fully at room temperature, and was detected by thin layer analysis (approximately 3 h), and then was quenched by methanol. Solvents were removed to obtain the residue. Finally, the (*R*)- MTPA ester of **5** (0.9 mg, t_{R} 17.0 min) was obtained from the residue by using RP HPLC (MeCN, 93%). By using the same method, the (*S*)-MTPA ester was also obtained.

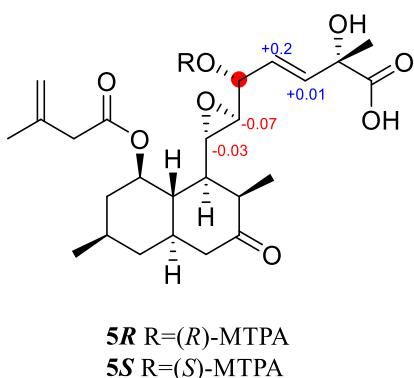

Figure S69. $\Delta\delta_{RS}$ values ($\delta_R - \delta_S$, in ppm) for **5R** and **5S**.

NMR calculation details

1. Methods

In general, conformational analyses were carried out via random searching in the Sybyl-X 2.0 using the MMFF94S force field with an energy cutoff of 5.0 kcal/mol.^[1] The results showed twenty-three lowest energy conformers. Subsequently, the conformers were re-optimized at the B3LYP-D3(BJ)/6-31G* level in PCM DMSO by the GAUSSIAN09 program.^[2] All conformers used for property calculations in this work were characterized to be stable point on potential energy surface (PES) with no imaginary frequencies. NMR shielding constants were computed using the GIAO method at the mPW1PW91/6-311+G** level in PCM DMSO by the GAUSSIAN09 program.^[2] Gibbs free energies for conformers were determined by using thermal correction at B3LYP-D3(BJ)/6-31G* level and electronic energies evaluated at the wB97M-V/def2-TZVP level in CPCM DMSO using ORCA^{[3][4]} Boltzmann weights

were computed using relative gibbs free energies. [5] The unscaled chemical shifts(δ_u) were computed using TMS (Tetramethylsilane) as a reference standard according to $\delta_u = \sigma_0 - \sigma_x$, where σ_x is the Boltzmann averaged shielding tensor (over all significantly populated conformations) and σ_0 is the shielding tensor of the TMS computed at the same level of theory employed for σ_x . The scaled chemical shifts(δ_s) were calculated as $\delta_s = (\delta_u - b) / m$, where m and b are the slope and intercept, respectively, deduced from a linear regression calculation on a plot of δ_u against δ_{exp} .

Theory and ECD calculation details.

In general, conformational analyses were carried out via random searching in the Sybyl-X 2.0 using the MMFF94S force field with an energy cutoff of 5 kcal/mol.^[1] The results showed eight lowest energy conformer for both compounds. Subsequently, geometry optimizations and frequency analyses were implemented at the B3LYP-D3(BJ)/6-31G* level in PCM methanol using ORCA5.0.1^[2] All conformers used for property calculations in this work were characterized to be stable point on potential energy surface (PES) with no imaginary frequencies. The excitation energies, oscillator strengths, and rotational strengths (velocity) of the first 60 excited states were calculated using the TD-DFT methodology at the PBE0/def2-TZVP level in PCM

methanol using ORCA5.0.1.^[2] The ECD spectra were simulated by the overlapping Gaussian function (half the bandwidth at 1/e peak height, sigma = 0.30 for all).^[3] Gibbs free energies for conformers were determined by using thermal correction at B3LYP-D3(BJ)/6-31G* level and electronic energies evaluated at the wB97M-V/def2-TZVP level in PCM methanol using ORCA5.0.1^[2] To get the final spectra, the simulated spectra of the conformers were averaged according to the boltzmann distribution theory and their relative Gibbs free energy (ΔG). By comparing the experiment spectra with the calculated model molecules, the absolute configuration of the only chiral center was determined to be.
