## 1. General information

<sup>1</sup>H and <sup>13</sup>C NMR spectra were measured at 400 and 100 MHz, respectively. The solvents used for NMR spectroscopy were CDCl<sub>3</sub>, using tetramethylsilane as the internal reference. HRMS (ESI) was determined by a HRMS/MS instrument. Enantiomeric excesses (*ee*) were determined by chiral high-performance liquid chromatography (chiral HPLC). The chiral columns used for the determination of enantiomeric excesses by chiral HPLC were Chiralpak columns. Optical rotation values were measured with instruments operating at  $\lambda = 589$  nm, corresponding to the sodium D line at the temperatures indicated. The X-ray source used for the single crystal X-ray diffraction analysis of compound **3aa** were GaK $\alpha$  ( $\lambda = 1.34139$ ), and the thermal ellipsoid was drawn at the 30% probability level. Analytical grade solvents for the column chromatography were distilled before use. All starting materials commercially available were used directly. Substrates **1-2** were synthesized according to the literature methods.<sup>1</sup>

## 11. Theoretical calculations

### Theoretical calculations of catalytic asymmetric formal (2 + 3) cycloaddition

**Computational Methods:** The DFT calculations of the possible transition states and intermediates in the reactions were performed by using the Gaussian 16 package.<sup>2</sup> The geometry optimizations of minima and transition states were carried out at the B3LYP-D3<sup>3</sup> with a Becke–Johnson (BJ)<sup>4</sup> damping function and the 6-31G(d)<sup>5</sup> basis set. The vibrational frequencies were computed at the same level to check whether each optimized structure is an energy minimum (zero imaginary frequency) or a transition state (one imaginary frequency) and to evaluate its zero-point vibration energy (ZPE) and thermal corrections at 298 K in kcal·mol<sup>-1</sup>. The single-point energies and solvent effects in ethylethanoate were computed with the dispersion-corrected density functional method B3LYP-D3 with a Becke–Johnson (BJ) damping function and the 6-311+G (d,p) basis set using the SDM solvation model.<sup>6</sup> DFT-optimized structures are illustrated using CYLView.<sup>7</sup>

cycloaddition, the key transition states **TS5** and **TS5'** of the diastereoselectivity-determining step were compared. Obviously, the H-bonds between CPA (*S*)-**5d** and the intermediate in **TS5** (1.589 Å and 1.770 Å) are shorter than those in **TS5'** (1.688 Å and 1.790 Å), which implied that the hydrogen-bonding interactions between (*S*)-**5d** and the intermediate in **TS5** are stronger than those in **TS5'**. Additionally, the Gibbs free energy of **TS5'** (-0.46 kcal·mol<sup>-1</sup>) is higher than that of **TS5** (-6.93 kcal·mol<sup>-1</sup>), and the energy difference between the two transition states is 6.47 kcal·mol<sup>-1</sup>. These results explained the excellent diastereoselectivity during the step of intramolecular addition and the formation of (*1R,3R*)-**3aa** as a major product.
