1. Experimental section

1.1 General information: Chemicals and reagents were purchased from commercial suppliers (Merck, GLR innovations, BLD pharm, Spectrochem) and used without further purification. Thin layer chromatography (TLC) was performed using pre-coated silica-plates purchased from Merck (silica gel 60 PF254, 0.25 mm). Column chromatography was performed using silica gel 100-200 mesh. NMR spectra were recorded in CDCl_3 at room temperature, on JEOL JNM-ECS400 spectrometer at operating frequencies of 400 MHz (^1H) or 100 MHz (^{13}C) as indicated in the individual spectrum. Chemical shifts (δ) are given in ppm relative to residual solvent (chloroform $\delta = 7.26$, 1,1,2,2-tetrachloroethane $\delta = 6.00$ ^1H , and $\delta = 77.16$ for proton-decoupled ^{13}C NMR), and coupling constants (J) are expressed in hertz (Hz). Multiplicity is tabulated as s for singlet, d for doublet, dd for doublet of doublet, t for triplet, q for quartet and m for multiplet. Structural assignments were made with additional information from gCOSY, and gNOESY experiments. High-resolution mass spectra (HRMS) were recorded using electrospray ionization (ESI) methods on Waters (XEVO G2-XS QTOF) mass spectrometer. UV-vis-NIR spectra were recorded in JASCO V-770 spectrophotometer. Cyclic voltammetry measurements of **5** (0.001 M) was performed using an electrochemical analyzer potentiostat model CHI-1115C from CH Instruments with a conventional three-electrode cell at 298 K under a nitrogen atmosphere at a scan rate of 50 mV/s. This electrochemical cell contains a platinum (Pt) disk (disk shaped with 2-mm diameter) as a working electrode, Pt wire as a counter electrode, and silver (Ag) wire as a pseudo-reference electrode. The Pt working electrode was polished with 1.0 micron α -alumina polishing powder in a figure-eight motion. Electrolyte solution (0.1 M) was prepared by dissolving tetrabutylammonium hexafluorophosphate (Bu_4NPF_6) in 5 mL dry dichloromethane (DCM). The DCM solution was degassed by bubbling nitrogen gas for 10 minutes prior to measurements. The direction of initial scan was chosen as reductive, with the initial potential values set at zero for **5** and switching between negative potential (-1.2 V) first, and then going to positive potential (1.4 V), and finally returning to zero (vs Ag wire). The potential was externally calibrated against the ferrocene/ferrocenium (Fc/Fc^+) couple (0.43 V). Melting points were determined using Cole-Parmer MP 250D-P melting point analyzer. X-band electron paramagnetic resonance (EPR) spectra were recorded using an EMX MICRO X Bruker EPR instrument.

1.2 Syntheses and characterization data

2,2'-([9,9'-bifluorenylidene]-2,2'-diyl)dibenzaldehyde (8): An oven-dried thick-walled glass tube was charged with pre-synthesized **6** (800 mg, 1.65 mmol), (2-formylphenyl)boronic acid (987 mg, 6.58 mmol) **7**, NaHCO₃ (2.76 g, 32.91 mmol), tetrahydrofuran (8 mL), distilled water (0.6 mL) and purged with N₂ for 30 mins. Pd₂(dba)₃ (151 mg, 0.164 mmol), and [(*t*-Bu)₃PH]BF₄ (191 mg, 0.658 mmol) were added subsequently and the resulting mixture was heated at 80 °C using an oil bath for 12 h. After cooling to room temperature, the THF was evaporated, water was added and the resultant mixture was extracted with DCM (3 x 50 mL). The crystal was kept at 298 K during data collection. Data acquisition as well as extraction of data was accomplished by utilizing Bruker Apex-3 and Bruker SAINT software packages using a narrow -frame algorithm.⁷ By utilizing OLex2,⁸ the crystal structure was solved with the help of olex2.solve⁹ structure solution program by employing intrinsic Phasing methods and crystal structure refinement was done with the SHELXL¹⁰ refinement package by putting into use Least Squares minimization. Refinement of all non-hydrogen atoms was completed with the help of anisotropic thermal parameters.

4. Photostability test

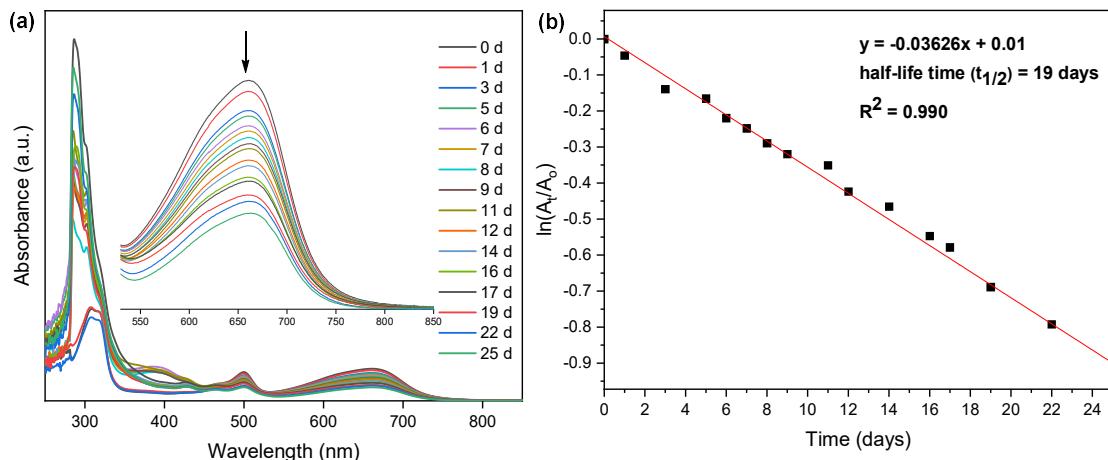

Fig. S13 a) Absorption spectral changes under ambient light conditions for compound **5** in toluene (0 days to 25 days); b) Fitting with first-order kinetics.

The half-life ($t_{1/2}$) of was determined according to the following equation:

$$t_{1/2} = \frac{\ln 2}{0.03626} = 19 \text{ days}$$

To check the photostability of final compound **5**, solution of known concentration of **5** in toluene was exposed to ambient light (under normal lab light condition and temperature). It leads to the gradual decomposition of **5** in solution, resulting in the decrease of the absorbance at longer wavelength (661 nm) region.

5. EPR measurement and Bleaney-Bowers plot

To get the ground state spin multiplicity and the energy separation between the singlet and triplet state, VT -EPR experiments were carried out using the solid sample of **5** displaying $g_e = 2.0043$. The modified Bleaney-Bowers equation was used to fit the IT against the T data points to get the energy separation between the singlet and triplet spin state of the diradicaloid species.

$$IT = \frac{2\rho N_A g^2 \beta^2}{k_b} * \frac{1}{3 + \exp\left(-\frac{2J}{k_b T}\right)} + \frac{(1-\rho)N_A g^2 \beta^2}{2k_b}$$

Here, $2J$ is the energy separation between singlet and triplet state (ΔE_{S-T}), ‘ I ’ is the EPR intensity, ‘ T ’ is the temperature in Kelvin scale, g is the g factor, N_A is the Avogadro constant, β is the Bohr magneton, k_b is the Boltzmann constant, and ρ is the paramagnetic purity.

The IT vs. T data set was fitted according to the below equation using Origin 2021 software package.

$$IT = \frac{a}{3 + \exp\left(-\frac{b}{T}\right)} + c$$

$$a = \frac{2\rho N_A g^2 \beta^2}{k_b}; b = \frac{2J}{k_b}; c = \frac{(1-\rho)N_A g^2 \beta^2}{2k_b}$$

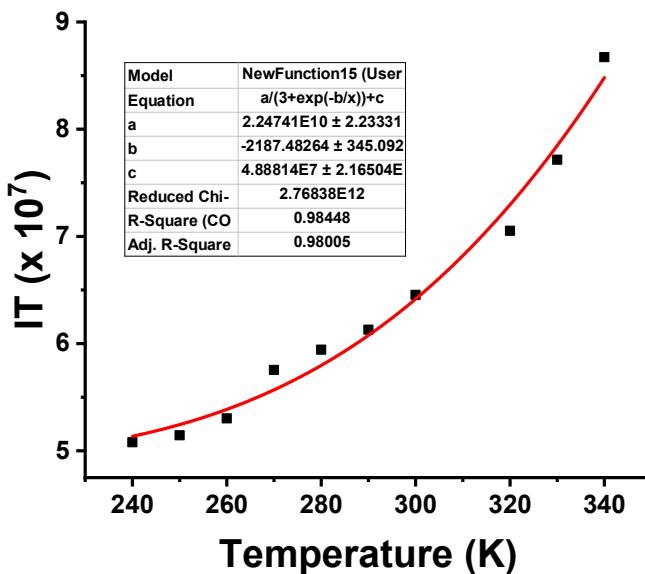

Fig. S14 Bleaney-Bowers plot for **5**.

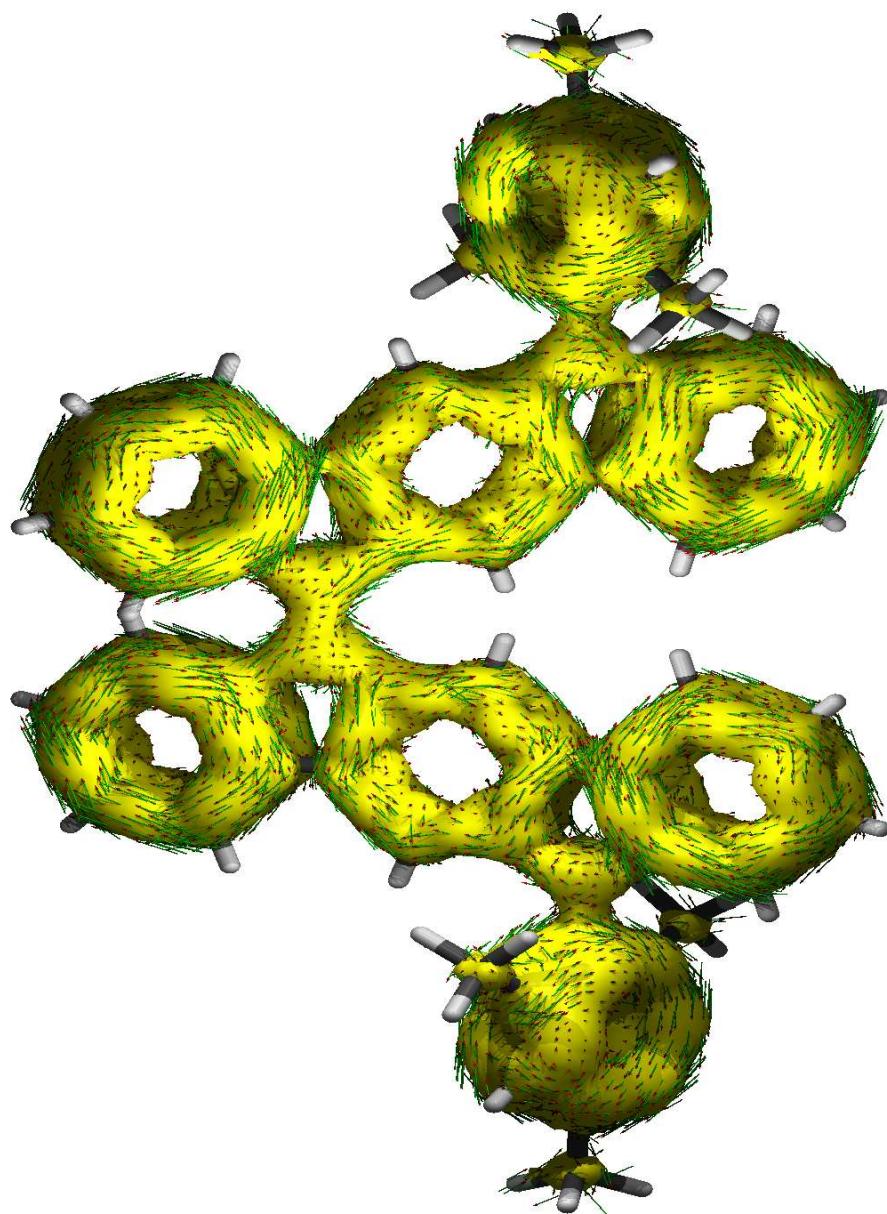

$$b = -2187.48 \pm 345.09;$$

$$2J = k_B * b = -4.35 \pm 0.6 \text{ kcal/mol}$$

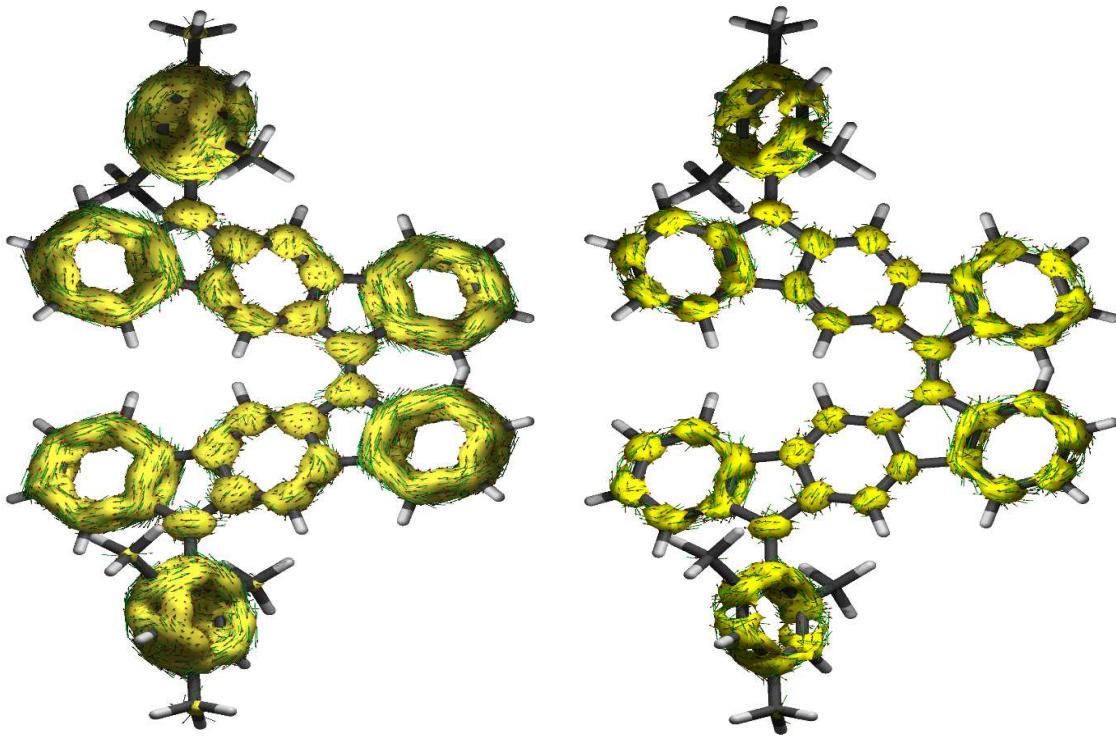

The experimental energy gap ($\Delta E_{\text{s-T}}$) between the singlet ground state and the excited triplet state is -4.35 ± 0.6 kcal/mol.

DFT-optimized C-C bond lengths of ground state open-shell structure **5**

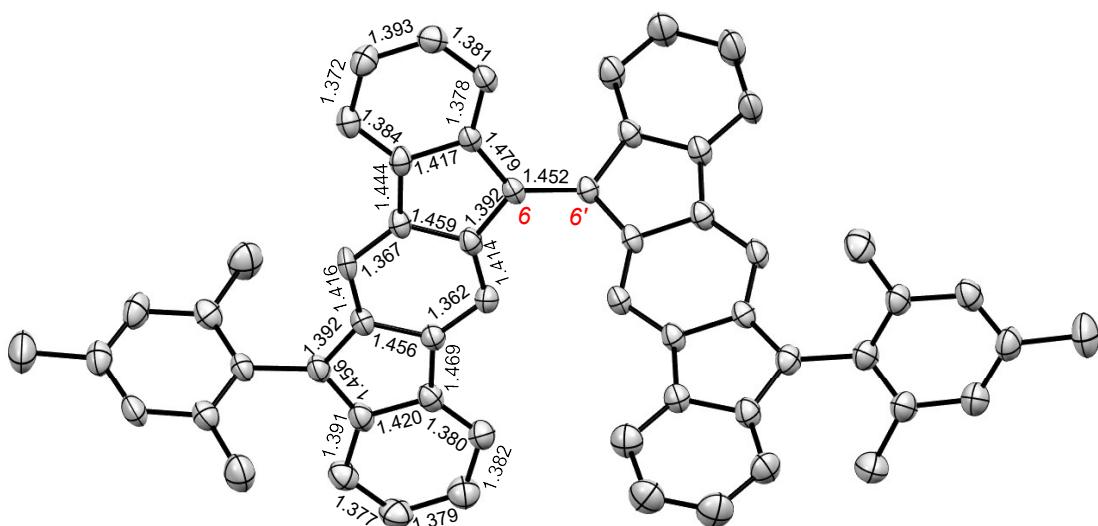

Comparison of X-ray crystallographic C-C bond lengths of **4** and **5**

Compound 4:

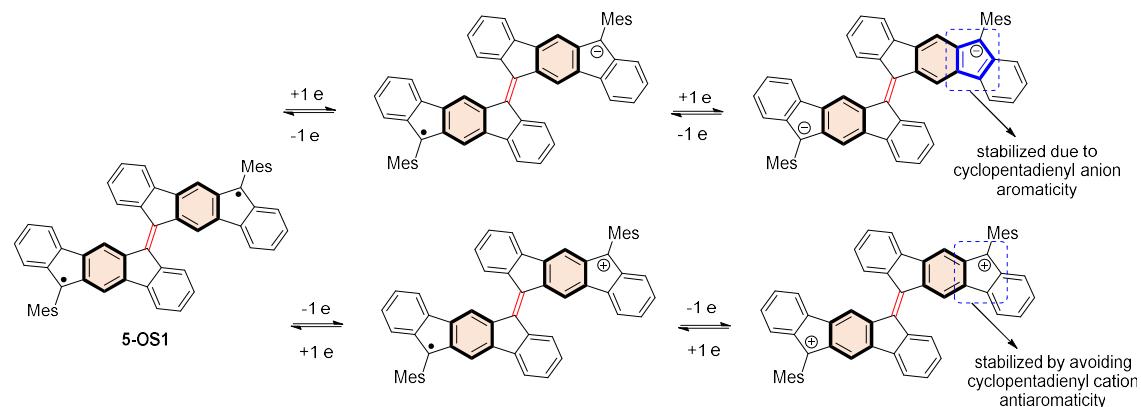

Compound 5:

Explanation of four-stage redox amphotericity:

The diradicaloid ground state ($y_0 = 0.268$) of **5** is clearly evident from the cyclic voltammetry and differential pulse voltammetry (Fig. 5b). The excellent reversibility during oxidation (facile electron ejection) and reduction (facile electron injection) events showing sequential one-electron transfer processes can be explained through the diradical-like structure **5-OS1**, as shown below. During reduction, electrons can be injected easily at lower reduction potential (low-lying LUMO = -3.80 eV) as formation of locally aromatic cyclopentadienyl anions (shown below) in the five membered rings can be favored. During oxidation, the double bond arrangement in benzene rings became such that it avoids formation of locally antiaromatic cyclopentadienyl cation (shown below) in the five membered rings.
